Invariants of links and 3-manifolds that count graph configurations

https://doi.org/10.5802/wbln.33
Invariants of links and 3-manifolds that count graph configurations

CHRISTINE LESCOP

Abstract

We present ways of counting configurations of uni-trivalent Feynman graphs in 3-manifolds in order to produce invariants of these 3-manifolds and of their links, following Gauss, Witten, Bar-Natan, Kontsevich and others. We first review the construction of the simplest invariants that can be obtained in our setting. These invariants are the linking number and the Casson invariant of integer homology 3-spheres. Next we see how the involved ingredients, which may be explicitly described using gradient flows of Morse functions, allow us to define a functor on the category of framed tangles in rational homology cylinders. Finally, we describe some properties of our functor, which generalizes both a universal Vassiliev invariant for links in the ambient space and a universal finite type invariant of rational homology 3-spheres.

Introduction

These notes are the notes of a series of lectures given in Pisa in February 2020 for Winter Braids. They contain all what has been said during the lectures, and more.

They present ways of counting configurations of uni-trivalent (Feynman) graphs in 3-manifolds in order to produce invariants of these 3-manifolds and of their links, following Gauss, Witten, Bar-Natan, Kontsevich and others. We first review the construction of the simplest invariants that can be obtained in our setting, in Section 1. These invariants are the linking number and the Casson invariant of integer homology 3-spheres. Next we see how the involved ingredients, which may be explicitly described using gradient flows of Morse functions, allow us to define an invariant \( Z \) of framed tangles in rational homology cylinders in Section 2. Finally, in Section 3, we describe some properties of our functorial invariant \( Z \), which generalizes both a universal Vassiliev invariant for links in the ambient space and a universal finite type invariant of rational homology 3-spheres.

For more details about the presented material, we refer the reader to the book [Les20], where the above functor \( Z \) has been constructed, and where all its mentioned properties are carefully proved. These notes may also be used as an introduction or as a reading guide to [Les20].

I warmly thank the organisers of the great session 2020 of Winter Braids, and the referee for her/his careful reading and her/his helpful comments.

1. On the linking number and the Theta invariant

The modern powerful invariants of links and 3–manifolds that are studied in these series of lectures can be thought of as generalizations of the linking number. In this section, we warm up by defining this classical basic invariant in several ways. This allows us to introduce conventions and methods that will be useful throughout these notes.

1.1. The linking number as a degree

Let \( S^1 \) denote the unit circle of the complex plane \( C \).

\[
S^1 = \{ z \in C, |z| = 1 \}.
\]

Consider a \( C^\infty \) embedding

\[
J \cup K : S^1 \cup S^1 \hookrightarrow \mathbb{R}^3
\]

of the disjoint union \( S^1 \cup S^1 \) of two circles into the ambient space \( \mathbb{R}^3 \) as the one pictured in Figure 1.1. Such an embedding represents a 2–component link. Each of the embeddings \( J : S^1 \hookrightarrow \mathbb{R}^3 \) and \( K : S^1 \hookrightarrow \mathbb{R}^3 \) represents a knot.

![Figure 1.1: A 2–component link in \( \mathbb{R}^3 \)](image-url)
The link embedding \( J \cup K \) induces the Gauss map

\[
p_JK : \quad S^1 \times S^1 \to S^2
\]

\[
(w, z) \quad \mapsto \quad \frac{1}{\|z - J(w)\|} (K(z) - J(w))
\]

**Definition 1.1.** The Gauss linking number \( lk_G(J, K) \) of the disjoint knots \( J(S^1) \) and \( K(S^1) \), which are simply denoted by \( J \) and \( K \), is the degree of the Gauss map \( p_JK \).

There are several (fortunately equivalent) definitions of the degree for a continuous map between two closed (i.e. connected, compact, without boundary) oriented manifolds of the same dimension. Let us quickly recall our favorite one for these lectures, where we work with smooth manifolds.

**Definition 1.2.** A point \( y \) is a regular value of a smooth map \( p : M \to N \) between two smooth manifolds \( M \) and \( N \), if \( y \in N \) and, for any \( x \in p^{-1}(y) \), the tangent map \( T_xp \) at \( x \) is surjective\(^1\), and, when the boundary \( \partial M \) of \( M \) is non-empty, and possibly stratified\(^2\), the restriction of the tangent map \( T_p \) to the tangent space of \( \partial M \) or to the stratum of \( x \) is also surjective for any \( x \in \partial M \cap p^{-1}(y) \).

An orientation of a real vector space \( V \) of positive dimension is a basis of \( V \) up to a change of basis with positive determinant. When \( V = \{0\} \), an orientation of \( V \) is an element of \( \{-1, 1\} \). An orientation of a smooth \( n \)-manifold is an orientation of its tangent space at each point, defined in a continuous way. A local diffeomorphism \( h \) of \( \mathbb{R}^n \) is orientation-preserving at \( x \) if and only if the Jacobian determinant of its derivative \( T_xh \) is positive. If the transition maps \( \phi_i \circ \phi_j^{-1} \) of an atlas \( \{(\phi_i)_{i \in I}\} \) of a manifold \( M \) are orientation-preserving (at every point) for \( \{i, j\} \subset I \), then the manifold \( M \) is oriented by this atlas. Unless otherwise mentioned, all manifolds are oriented in these notes.

When \( M \) and \( N \) are oriented, \( M \) is compact and the dimension of \( M \) coincides with the dimension of \( N \), the differential degree \( \deg_y(p) \) of \( p \) at a regular value \( y \) of \( p \) is the (finite) sum running over the \( x \in p^{-1}(y) \) of the signs of the determinants of \( T_xp \). In this case, this differential degree can be extended to a continuous function \( \deg(p) \) from the complement \( N \setminus p(\partial M) \) of the image of the boundary \( \partial M \) of \( M \) to \( \mathbb{Z} \). See [Les20, Lemma 2.3]. In particular, when the boundary of \( M \) is empty and \( N \) is connected, the function \( \deg(p) \) is constant, and its value is the degree of \( p \). See [Mil97, Chapter 5].

The Gauss linking number \( lk_G(J, K) \) can be computed from a link diagram as in Figure 1.1 as follows. It is the differential degree of \( p_JK \) at the vector \( Y \) that points towards us. The set \( p_JK^{-1}(Y) \) consists of the pairs of points \( (w, z) \) where the projections of \( J(w) \) and \( K(z) \) coincide, and \( J(w) \) is under \( K(z) \). They correspond to the crossings \( \begin{array} \cdot \cdot \cdot \end{array} \) of the diagram.

In a diagram, a crossing is positive if we turn counterclockwise from the arrow at the end of the upper strand towards the arrow of the end of the lower strand like \( \begin{array} \cdot \cdot \cdot \end{array} \). Otherwise, it is negative like \( \begin{array} \cdot \cdot \cdot \end{array} \).

For the positive crossing \( \begin{array} \cdot \cdot \cdot \end{array} \), moving \( J(w) \) along \( J \) following the orientation of \( J \), moves \( p_JK(w, z) \) towards the south-east direction \( TP_JKdw \), while moving \( K(z) \) along \( K \) following the

---

\(^1\)According to the Morse-Sard theorem [Hir94, Chapter 3, Theorem 1.3, p. 69], the set of regular values of such a map is dense. It is even residual, i.e. it contains the intersection of a countable family of dense open sets. Furthermore it is open if \( M \) is compact.

\(^2\)In these notes, manifolds are smoothly modelled on open subspaces of \( [0, 1]^n \), and covered by countably many such spaces. In particular their boundaries have strata, which correspond to the open faces of \( [0, 1]^n \). They have corners, which correspond to the points of \( [0, 1]^n \), and ridges, which correspond to the open faces of \( [0, 1]^n \) of dimension in \( \{1, \ldots, n-2\} \). For example, in dimension 3, the ridges correspond to the edges of the cube.
Christine Lescop

orientation of $K$, moves $p_{jk}(w,z)$ towards the north-east direction $T_{p_{jk}}dz$, so that the local orientation induced by the image of $p_{jk}$ around $y \in S^2$ is

![Diagram](image)

which is

Therefore, the contribution of a positive crossing to the degree is 1. It is easy to deduce that the contribution of a negative crossing is $(-1)$.

We have proved the following formula

$$\deg (p_{jk}) = \# \frac{j}{K} - \# \frac{k}{j},$$

where $\#$ stands for the cardinality—here $\# \frac{j}{K}$ is the number of occurrences of $\frac{j}{K}$ in the diagram—so that

$$lk_G(j, k) = \# \frac{j}{K} - \# \frac{k}{j}.$$ 

Similarly, $\deg (p_{jk}) = \# \frac{k}{j} - \# \frac{j}{k}$ so that

$$lk_G(j, k) = \# \frac{k}{j} - \# \frac{j}{k} = \frac{1}{2} \left( \# \frac{j}{K} + \# \frac{k}{j} - \# \frac{k}{J} - \# \frac{j}{K} \right),$$

and thus $lk_G(j, k) = lk_G(k, j)$.

In the example of Figure 1.1, $lk_G(j, k) = 2$. Let us give some further examples. For the positive Hopf link of Figure 1.2, $lk_G(j, k) = 1$. For the negative Hopf link, $lk_G(j, k) = -1$, and, for the Whitehead link, $lk_G(j, k) = 0$.

![Diagram](image)

Figure 1.2: The Hopf links and the Whitehead link

Since the differential degree of the Gauss map $p_{jk}$ is constant on the set of regular values of $p_{jk}$, $lk_G(j, k) = \int_{S^1 \times S^1} p_{jk}^*(\omega_5)$ for any 2-form $\omega_5$ on $S^2$ such that $\int_{S^2} \omega_5 = 1$.

Denote the standard area form of $S^2$ by $4\pi \omega_5^2$ so that $\omega_5^2$ is the homogeneous volume form of $S^2$ such that $\int_{S^2} \omega_5^2 = 1$. In 1833, Gauss defined the linking number of $J$ and $K$, as an integral [Gau77]. In modern notation, his definition may be expressed as

$$lk_G(j, k) = \int_{S^1 \times S^1} p_{jk}^*(\omega_5^2).$$

1.2. The linking number as an algebraic intersection

The boundary $\partial M$ of an oriented manifold $M$ is oriented by the outward normal first convention. If $x \in \partial M$ is in a smooth part of $\partial M$, the outward normal to $M$ at $x$ followed by an oriented basis of $T_x\partial M$ induce the given orientation of $M$. For example, the standard orientation of the disk in the plane induces the standard orientation of the circle, counterclockwise, as the following picture shows.
As another example, the sphere $S^2$ is oriented as the boundary of the ball $B^3$, which has the standard orientation induced by the right hand rule: (Thumb, index finger (2), middle finger (3)) of the right hand.

The tangent bundle to an oriented submanifold $A$ in a manifold $M$ at a point $x$ is denoted by $T_xA$. Two submanifolds $A$ and $B$ in a manifold $M$ are transverse$^3$ if at each intersection point $x$, $T_xM = T_xA + T_xB$. If two transverse submanifolds $A$ and $B$ in a manifold $M$ are of complementary dimensions (i.e. if the sum of their dimensions is the dimension of $M$), then the sign of an intersection point is $+1$ if $T_xM = T_xA @ T_xB$ as oriented vector spaces. Otherwise, the sign is $-1$. If $A$ and $B$ are compact and if $A$ and $B$ are of complementary dimensions in $M$, their algebraic intersection is the sum of the signs of the intersection points, and is denoted by $\langle A, B \rangle_M$.

For us, a rational chain (resp. integral chain) is a linear combination of (oriented) smooth manifolds with boundary, with coefficients in $\mathbb{Q}$ (resp. in $\mathbb{Z}$). Algebraic intersection bilinearly extends to pairs of transverse chains.

When $\mathbb{K}$ is $\mathbb{Z}$ or $\mathbb{Q}$, a $\mathbb{K}$-sphere is a compact oriented 3-dimensional manifold$^4$ $R$ with the same homology with coefficients in $\mathbb{K}$ as the standard unit sphere $S^3$ of $\mathbb{R}^4$. Q-spheres (resp. Z-spheres) are also called rational (resp. integer) homology 3-spheres. In these notes, we omit the 3 since the dimension of our homology spheres is always 3.

According to an easy case of a Thom theorem [Les20, Theorem 11.9], any knot $K$ in a Q-sphere $R$ bounds$^5$ an oriented rational chain in $R$. If $R$ is a Z-sphere, $K$ bounds an embedded surface$^6$, called a Seifert surface of the knot.

The simplest definition of the linking number of two disjoint knot embeddings in such a manifold is the following one.

**Definition 1.3.** The linking number $lk(J, K)$ of two disjoint knot embeddings $J$ and $K$ in a Q-sphere $R$ is the algebraic intersection $(J, \Sigma_K)_R$ of $J$ and a rational chain $\Sigma_K$ bounded by $K$.

We will see that $lk_G(J, K) = lk(J, K)$ for 2-component links in $\mathbb{R}^3 \subset S^3$ in Lemma 1.15. See also [Les20, Proposition 2.9].

In order to generalize the Gauss definition of the linking number to 2-component links in a rational homology sphere $R$, let us rephrase it.

As in Subsection 1.1, consider a two-component link $J \sqcup K : S^1 \sqcup S^1 \hookrightarrow \mathbb{R}^3$. This embedding induces an embedding

$$J \times K : S^1 \times S^1 \hookrightarrow (\mathbb{R}^3)^2 \setminus \text{diag}$$

$$(z_1, z_2) \mapsto (J(z_1), K(z_2))$$

into the 2-point configuration space

$$\tilde{C}_2(S^3) = (\mathbb{R}^3)^2 \setminus \text{diag}.$$ 

---

$^3$As shown in [Hir94, Chapter 3 (Theorem 2.4 in particular)], transversality is a generic condition.

$^4$Here, all manifolds are supposed to be smooth. Since any topological 3-manifold has a unique smooth structure (see [Ku99]), we do not specify “smooth” and we often only describe 3-manifolds up to homeomorphism.

$^5$The Poincaré duality ensures that this property characterizes Q-spheres among closed oriented 3-manifolds.

$^6$This property similarly characterizes Z-spheres among closed oriented 3-manifolds.
Consider the map
\[ p_{S^2} : \hat{c}_2(S^3) \to S^2 \]
\[ (x, y) \mapsto \frac{1}{\|y - x\|}(y - x). \]

The Gauss map \( p_{JK} \) of Section 1.1 is equal to \( p_{S^2} \circ (J \times K) \).

In particular, we can rewrite \( l_G(J, K) \) as another algebraic intersection, which will generalize to 2–component links in a rational homology sphere \( R \). For a regular value \( a \in S^2 \) of \( p_{JK} \),
\[ l_G(J, K) = \deg_{a} p_{JK} = (J \times K)(S^1 \times S^1), p_{S^2}^{-1}(a)|_{\hat{C}_2(S^3)} \]
where the preimages are oriented as follows. The normal bundle \( T_x M/\partial T_x A \) to \( A \) in \( M \) at \( x \) is denoted by \( N_x A \). It is oriented so that (a lift of an oriented basis of) \( N_x A \) followed by (an oriented basis of) \( T_x A \) induce the orientation of \( T_x M \). The orientation of \( N_x (A) \) is a coorientation of \( A \) at \( x \). The regular preimage of a submanifold under a map \( f \) is oriented so that \( f \) preserves the coorientations.

For any 2-form \( \omega_S \) on \( S^2 \) such that \( \int_{S^2} \omega_S = 1 \), we can also use the closed 2-form \( p_{S^2}^* (\omega_S) \) of \( \mathbb{R}^3^2 \setminus \) diag to write
\[ l_G(J, K) = \int_{S^1 \times S^1} p_{JK}^* (\omega_S) = \int_{(J \times K)(S^1 \times S^1)} p_{S^2}^* (\omega_S). \]

The closure of \( p_{S^2}^{-1}(a) \) in a compactification \( C_2(S^3) \) (defined in Section 1.3 below) of \( \hat{C}_2(S^3) \) is our first example of propagating chain or propagator. The closed 2-form \( p_{S^2}^* (\omega_S) \) extends to \( C_2(S^3) \) as an example of propagating form or propagator. Propagators are central ingredients in the construction of more general invariants of tangles in \( \mathbb{Q} \)-spheres that is presented in these notes.

### 1.3. Propagators

Let us first introduce the compact 2–point configuration spaces where propagators live. Their constructions use the following differential blow-ups.

**Definition 1.4.** Recall that the unit normal bundle of a submanifold \( C \) in a smooth manifold \( A \) is the fiber bundle over \( C \) whose fiber over \( x \in C \) is \( SN_x(C) = (N_x(C) \setminus \{0\})/\mathbb{R}^+ \), where \( \mathbb{R}^+ \) acts by scalar multiplication. A smooth submanifold transverse to the ridges of a smooth manifold \( A \) is a subset of \( C \) such that for any point \( x \in C \) there exists a smooth open embedding \( \phi \) from \( \mathbb{R}^C \times \mathbb{R}^e \times [0, 1]^d \to A \) such that \( \phi(0) = x \) and the image of \( \phi \) intersects \( C \) exactly along \( \phi(0 \times \mathbb{R}^e \times [0, 1]^d) \). Here \( c \) is the codimension of \( C \), \( d \) and \( e \) are integers, which depend on \( x \), and \( [0, 1]^d \) denotes the interval \( [0, 1]^d \). For us, blowing up such a compact submanifold \( C \) in \( A \) replaces \( C \) with its unit normal bundle in order to produce the smooth manifold \( BL(A, C) \) (with possible ridges) so that a chart \( \phi : \mathbb{R}^C \times \mathbb{R}^e \times [0, 1]^d \to A \) as above induces a chart \( \tilde{\phi} : ([0, \infty] \cdot S^{c-1}) \times \mathbb{R}^e \times [0, 1]^d \to BL(A, C) \). (The origin 0 of \( \mathbb{R}^C \) is replaced with the sphere \( \{0\} \) \( \times S^{c-1} \) of directions around it.)

Unlike blow-ups in algebraic geometry, this differential geometric blow-up creates boundaries. More precisely, we have the following proposition.

**Proposition 1.5.** Under the assumptions of the above definition, we have the following properties.

- \( BL(A, C) \) is diffeomorphic to the complement of an open tubular neighborhood of \( C \) (thought of as infinitely small).

- There is a canonical projection \( p_b : BL(A, C) \to A \), which restricts to a diffeomorphism from the preimage of \( A \setminus C \) to \( A \setminus C \).

- If \( A \) is compact, \( BL(A, C) \) is a compactification of \( A \setminus C \).
• If the boundary \( \partial A \) of \( A \) is empty, then the boundary of \( \mathcal{B}(A, C) \) is the unit normal bundle of \( C \) in \( A \), and the interior \( \mathcal{B}(A, C) \setminus \partial \mathcal{B}(A, C) \) of \( \mathcal{B}(A, C) \) is \( A \setminus C \).

**Examples 1.6.** Local models are given by the following elementary blow-ups \( \mathcal{B}(\mathbb{R}^c, 0) \cong [0, \infty[ \times S^{c-1} \) and \( \mathcal{B}(\mathbb{R}^c \times A, 0 \times A) \cong [0, \infty[ \times S^{c-1} \times A \).

In Figure 1.3, we see the result of first blowing up \((0,0)\) in \(\mathbb{R}^2\), and next blowing up the closures in \(\mathcal{B}(\mathbb{R}^2, (0,0))\) of \(\{0\} \times \mathbb{R}^*\), \(\mathbb{R}^* \times \{0\}\) and the diagonal of \((\mathbb{R}^*)^2\).

![Figure 1.3: Iterated blow-ups of \(\mathbb{R}^2\)](image)

We regard \(S^3\) as \(\mathbb{R}^3 \cup \{\infty\}\) or as two copies of \(\mathbb{R}^3\) identified along \(\mathbb{R}^3 \setminus \{0\}\) by the (exceptionally orientation-reversing) diffeomorphism \(x \mapsto x/\|x\|^2\). The blow-up \(\mathcal{B}(S^3, \infty)\) is diffeomorphic to the compact unit ball of \(\mathbb{R}^3\). As a set, \(\mathcal{B}(S^3, \infty) = \mathbb{R}^3 \cup S^2_\infty\) where \((-S^2_\infty)\) denotes\(^7\) the unit normal bundle to \(\infty\) in \(S^3\) and \(\mathcal{B}(S^3, \infty) = S^2_\infty\). There is a canonical orientation-preserving diffeomorphism \(p_\infty : S^2_\infty \rightarrow S^2\) such that \(x \in S^2_\infty\) is the limit in \(\mathcal{B}(S^3, \infty)\) of a sequence of points of \(\mathbb{R}^3\) approaching \(\infty\) along a line directed by \(p_\infty(x) \in S^2\).

Let \(R\) be a \(Q\)-\(S^3\) equipped with a point \(\infty \in R\). Identify a neighborhood of \(\infty\) in \(R\) with a neighborhood of \(\infty\) in \(S^3\). Let \(\tilde{R} = R \setminus \{\infty\}\). Define the configuration space \(C_2(R)\) to be the compact 6-manifold with boundary and ridges obtained from \(R^2\) by first blowing up \((0,\infty)\) in \(R^2\), and, by next blowing up the closures of \(\{\infty\} \times \tilde{R}\), \(\tilde{R} \times \{\infty\}\) and the diagonal of \(\tilde{R}^2\) in \(\mathcal{B}(R^2, (\infty,\infty))\).

In particular, \(\partial C_2(R)\) contains the unit normal bundle \((\frac{\tilde{R}^2}{\text{diag}(\tilde{R}^2)} \setminus \{0\})/(\mathbb{R}^* \times \{\infty\})\) to the diagonal of \(\tilde{R}^2\). This bundle is canonically isomorphic to the unit tangent bundle \(\tilde{U}\tilde{R}\) to \(\tilde{R}\) via the map \(((x,y)) \mapsto \{y-x\})\). We have
\[
\partial C_2(R) = p_\infty^{-1}(\infty,\infty) \cup (S^2_\infty \times \tilde{R}) \cup (\tilde{R} \times S^2_\infty) \cup \tilde{U}\tilde{R}
\]
and
\[
(\tilde{C}_2(R) \overset{\text{def}}{=} C_2(R) \setminus \partial C_2(R)) = \tilde{R}^2 \setminus \text{diag}(\tilde{R}^2).
\]

The following proposition is [Les20, Lemma 3.5].

**Proposition 1.7.** Let \(i_{S^2}\) denote the antipodal map of \(S^2\). The \(S^2\)-valued map \(p_{S^2} : (x,y) \mapsto \frac{1}{\|y-x\|}(y-x)\) extends smoothly from \(\tilde{C}_2(R^3)\) to \(C_2(S^3)\), and its extension \(p_{S^2}\) satisfies:
\[
p_{S^2} = \begin{cases} 
i_{S^2} \circ p_\infty \circ p_1 & \text{on } S^2_\infty \times \mathbb{R}^3 \\
p_\infty \circ p_2 & \text{on } \mathbb{R}^3 \times S^2_\infty \\
p_2 & \text{on } \mathbb{U}\mathbb{R}^3=\mathbb{R}^3 \times S^2
\end{cases}
\]

where \(p_1\) and \(p_2\) respectively denote the projections on the first and second factor, with respect to the above expressions.

Also note the following lemma\(^8\).

**Lemma 1.8.** \(C_2(S^3)\) is homotopy equivalent to \(S^2\).

\(^7\)The minus sign in \((-S^2_\infty)\) reflects an orientation reversal.

\(^8\)More information about the homotopy groups and the homology of spaces of injective configurations of points in \(\mathbb{R}^n\) or in \(S^n\) can be found in the book [FH01] by Fadell and Husseini.
Proof: $C_2(S^3)$ is homotopy equivalent to its interior $((\mathbb{R}^3)^2 \setminus \text{diag})$, which is homeomorphic to $\mathbb{R}^3 \times \{0\}$ via the map

$$(x, y) \mapsto (x, \|y - x\|, p_{S^2}(x, y)).$$

\[\Box\]

We regard $\mathbb{R}^3$ as $\mathbb{C} \times \mathbb{R}$, where $\mathbb{C}$ is thought of as horizontal. Let $\mathbb{C}_0 = D^2 \times [0, 1]$ be the standard cylinder of $\mathbb{R}^3$, where $D^2$ is the unit disk of $\mathbb{C}$. Let $\mathbb{C}_0^C$ (resp. $\mathbb{C}_0$) denote the closure of the complement of $\mathbb{C}_0$ in $S^3$ (resp. in $\mathbb{R}^3$). Here, a rational homology cylinder (or $\mathbb{Q}$–cylinder) is a compact oriented 3-manifold whose boundary neighborhood is identified with a boundary neighborhood $N(\partial \mathbb{C}_0)$ of $\mathbb{C}_0$, and that has the same rational homology as a point. Any $\mathbb{Q}$–sphere $\mathbb{R}$ (may and) will be viewed as the union $\mathbb{R}(\mathcal{C})$ of $\mathbb{C}_0^C$ and of a rational homology cylinder $\mathcal{C}$ glued along $\partial \mathbb{C}_0$. It suffices to choose a point $\infty$ and a diffeomorphism that identifies a neighborhood of this point in $\mathbb{R}$ with $\mathbb{C}_0^C$ to obtain such a decomposition.

Definition 1.9. Let $\tau$ denote the standard parallelization of $\mathbb{R}^3$. A parallelization of $\tilde{\mathbb{R}}$

$$\tau: \tilde{\mathbb{R}} \times \mathbb{R}^3 \to \tilde{T}\tilde{\mathbb{R}}$$

is asymptotically standard if it coincides with $\tau$ on $\mathbb{C}_0$. According to [Les20, Proposition 5.5], asymptotically standard parallelizations exist for any $\mathbb{R}$. Such a parallelization identifies $U\tilde{\mathbb{R}}$ with $\tilde{\mathbb{R}} \times S^2$.

An asymptotic rational homology $\mathbb{R}^3$ is a pair $(\tilde{\mathbb{R}}, \tau)$ where $\tilde{\mathbb{R}}$ is a punctured rational homology sphere with a decomposition $\tilde{\mathbb{R}} = \mathcal{C} \cup\mathbb{C}_0 \mathbb{C}_0^C$ as above, equipped with an asymptotically standard parallelization $\tau$.

In what follows, we fix such an asymptotic rational homology $\mathbb{R}^3$ $(\tilde{\mathbb{R}} = \tilde{\mathbb{R}}(\mathcal{C}) = \mathcal{C} \cup\mathbb{C}_0 \mathbb{C}_0^C, \tau)$ with its decomposition.

Lemma 1.10. The parallelization $\tau$ of $\tilde{\mathbb{R}}$ induces the continuous map $p_\tau: \partial \mathbb{C}_2(\mathcal{R}) \to S^2$ such that

$$p_\tau = \begin{cases} \quad l_{S^2} \circ p_\infty \circ p_1 & \text{on } S^2_{\infty} \times \tilde{\mathbb{R}} \\ p_\infty \circ p_2 & \text{on } \tilde{\mathbb{R}} \times S^2_{\infty} \\ p_2 & \text{on } U\tilde{\mathbb{R}} \equiv \tilde{\mathbb{R}} \times S^2 \\ p_{S^2} & \text{on } p_{S^2}^{-1}(\infty, \infty) \end{cases}$$

where $p_1$ and $p_2$ denote the projections on the first and second factor, respectively, with respect to the above expressions.

Proof: This is a corollary of Proposition 1.7. \[\Box\]

Lemma 1.11. $H_*(\mathbb{C}_2(\mathcal{R}); \mathbb{Q}) \cong H_*(S^2; \mathbb{Q})$ and $H_2(\mathbb{C}_2(\mathcal{R}); \mathbb{Q})$ is generated by the class $[S]$ of a fiber $U\tilde{\mathbb{R}}$ of the bundle $U\tilde{\mathbb{R}}$, oriented as the boundary of a ball of $T_x\tilde{\mathbb{R}}$.

Proof: The space $\mathbb{C}_2(\mathcal{R})$ is homotopy equivalent to its interior $((\tilde{\mathbb{R}})^2 \setminus \text{diag})$, where $\tilde{\mathbb{R}}$ has the rational homology of a point. The rational homology of $((\tilde{\mathbb{R}})^2 \setminus \text{diag})$ can be computed like the rational homology of $((\mathbb{R}^3)^2 \setminus \text{diag})$, which is isomorphic to the rational homology of $S^2$ thanks to Lemma 1.8. \[\Box\]

Definition 1.12. A volume-one form of $S^2$ is a 2-form $\omega_S$ of $S^2$ such that $\int_{S^2} \omega_S = 1$. (See [Les20, Appendix B] for a short survey of differential forms and de Rham cohomology.) Let $(\tilde{\mathbb{R}}, \tau)$ be an asymptotic rational homology $\mathbb{R}^3$. Recall the map $p_\tau: \partial \mathbb{C}_2(\mathcal{R}) \to S^2$ of Lemma 1.10. A propagating form of $(\mathbb{C}_2(\mathcal{R}), \tau)$ is a closed 2-form $\omega$ on $\mathbb{C}_2(\mathcal{R})$ whose restriction to $\partial \mathbb{C}_2(\mathcal{R})$ is equal to $p_\tau^{-1}(\omega_S)$ for some volume-one form $\omega_S$ of $S^2$. A propagating chain of $\mathbb{C}_2(\mathcal{R})$ is a rational 4-chain $P$ of $\mathbb{C}_2(\mathcal{R})$ such that $\partial P \subset \partial \mathbb{C}_2(\mathcal{R})$ and $\partial P \cap (\partial \mathbb{C}_2(\mathcal{R}) \cup U\tilde{\mathbb{R}}) = p_{\tau|\partial \mathbb{C}_2(\mathcal{R})\cup U\tilde{\mathbb{R}}}^{-1}(a)$ for some $a \in S^2$. This definition does not depend on $\tau$. A propagating chain of $(\mathbb{C}_2(\mathcal{R}), \tau)$ is a propagating chain of $\mathbb{C}_2(\mathcal{R})$ such that $\partial P = p_\tau^{-1}(a)$ for some $a \in S^2$. Propagating chains and propagating forms are simply called propagators when their nature is clear from the context.

Christine Lescop

I-8
Example 1.13. Recall the map \( pr_2 : C_2(S^3) \to S^2 \) of Proposition 1.7. As already announced, for any \( a \in S^2 \), \( pr_2^{-1}(a) \) is a propagating chain of \( (C_2(S^3), \tau_3) \), and for any volume-one form \( \omega_S \) of \( S^2 \), \( pr_2^{*}(\omega_S) \) is a propagating form of \( (C_2(S^3), \tau_3) \).

For our general \( \mathbb{Q}-\) sphere \( R \), propagating chains exist because the 3-cycle \( pr_3^{-1}(a) \) of \( aC_2(R) \) bounds in \( C_2(R) \) since \( H_3(C_2(R); \mathbb{Q}) = 0 \), according to Lemma 1.11. Dually, propagating forms exist because the restriction induces a surjective map \( H^2(C_2(R); \mathbb{R}) \to H^2(aC_2(R); \mathbb{R}) \) since \( H^3(C_2(R), aC_2(R); \mathbb{R}) = 0 \).

When \( R \) is a \( \mathbb{Z}-\) sphere, there exist propagating chains that are smooth 4-manifolds properly embedded in \( C_2(R) \). See [Les20, Corollary 11.10]. Explicit propagating chains associated with Heegaard splittings, which were constructed with Greg Kuperberg in [Les15a], are described in Section 1.5 below. They are integral chains multiplied by \( \frac{1}{|H_1(R; \mathbb{Z})|} \), where \( |H_1(R; \mathbb{Z})| \) is the cardinality of \( H_1(R; \mathbb{Z}) \).

Lemma 1.14. Let \((\hat{R}, \tau)\) be an asymptotic rational homology \( \mathbb{R}^3 \). Let \( C \) be a two-cycle\(^9\) of \( C_2(R) \). For any propagating chain \( P \) of \( C_2(R) \) transverse to \( C \) and for any propagating form \( \omega \) of \( (C_2(R), \tau) \),

\[
[C] = \int_C \omega[S] = \langle C, P \rangle_{C_2(R)}[S]
\]

in \( H_2(C_2(R); \mathbb{Q}) = \mathbb{Q}[S] \).

Proof: Fix a propagating chain \( P \). The algebraic intersection \( \langle C, P \rangle_{C_2(R)} \) depends only on the homology class \([C]\) of \( C \) in \( C_2(R) \). Similarly, since \( \omega \) is closed, \( \int_C \omega \) only depends on \([C]\). (Indeed, if \( C \) and \( C' \) cobound a chain \( D \) transverse to \( P \), \( C \cap P \) and \( C' \cap P \) cobound \( \pm(D \cap P) \), and \( \int_{d=\Delta-C} \omega = \int_D d\omega \) according to Stokes’ theorem.) Furthermore, the dependence on \([C]\) is linear. Therefore it suffices to check the lemma for a chain that represents the canonical generator \([S]\) of \( H_2(C_2(R); \mathbb{Q}) \). Any fiber of \( UR \) is such a chain.

\( \square \)

A meridian of a knot embedding \( K \) is the (oriented) boundary of a disk that intersects \( K \) once with a positive sign, as in Figure 1.4.

![Figure 1.4: A meridian \( m_K \) of a knot \( K \)](image)

Lemma 1.15. Let \( J \cup K \) be a two-component link embedding of \( \hat{R} \). The torus \( J \times K = (J \times K)(S^1 \times S^1) \) is homologous to \( lk(J, K)[S] \) in \( H_2(C_2(R); \mathbb{Q}) \). For any propagating chain \( P \) of \( C_2(R) \) transverse to \( J \times K \) and for any propagating form \( \omega \) of \( (C_2(R), \tau) \),

\[
\text{lk}(J, K) = \int_{J \times K} \omega = \langle J \times K, P \rangle_{C_2(R)}.
\]

If \( \hat{R} = \mathbb{R}^3 \), then the linking number \( \text{lk}(J, K) \) of Definition 1.3 is the degree \( \text{lk}_G(J, K) \) of the Gauss map \( p_{JK} \).

Proof: When \( \hat{R} = \mathbb{R}^3 \),

\[
\text{lk}_G(J, K) = \text{deg}_d(p_{JK}) = \langle J \times K, p_{S^2}^{-1}(a) \rangle_{C_2(S^3)}
\]

\(^9\)A \( d-\)cycle is a chain of dimension \( d \) whose algebraic boundary is equal to zero. In other words, it is a \( d \)-chain such that the integral of any form of degree \( d-1 \) along its boundary is zero.
so that $J \times K$ is homologous to $lk_G(J, K)[S] \in H^2(C_2(S^3); \mathbb{Q})$ according to Lemma 1.14, with the propagator $p^{-1}_\tau(a)$ of Example 1.13. For an arbitrary $R$, define $lk_G(J, K)$ so that $J \times K$ is homologous to $lk_G(J, K)[S] \in H^2(C_2(R); \mathbb{Q})$. Recall from Definition 1.3 that $lk(J, K)$ is the algebraic intersection $(J, \Sigma_K,J)$ of $J$ and a rational chain $\Sigma_K$ bounded by $K$. Lemma 1.14 reduces the proof of Lemma 1.15 to the proof that $lk(J, K)$ and $lk_G(J, K)$ coincide for any two-component link $J \cup K$ of $R$. Note that the definitions of $lk(J, K)$ and $lk_G(J, K)$ make sense when $J$ and $K$ are disjoint links. If $J$ has several components $J_i$, for $i = 1, \ldots, n$, then $lk_G(U_{i=1}^n J_i, K) = \sum_{i=1}^n (k(G, J_i, K) and lk(U_{i=1}^n J_i, K) = \sum_{i=1}^n k(J_i, K)$. There is no loss of generality in assuming that $J$ is a knot for the proof, which we do. The chain $\Sigma_K$ provides a rational cobordism $C$ in $R \setminus J$ between $K$ and a combination of meridians of $J$, which is homologous to $lk(J, K)[m_j]$. The product rational cobordism $J \times C$ in $R^2 \setminus \operatorname{diag}(R^2)$ allows us to see that $[J \times K] = lk(J, K)[j \times m_j]$ in $H_2(R^2 \setminus \operatorname{diag}(R^2); \mathbb{Q})$. Similarly, a chain $\Sigma_f$ bounded by $f$ provides a rational cobordism between $f$ and a meridian $m_f$ of $m_J$ so that $[J \times m_f] = [m_f \times m_J]$ in $H_2(R^2 \setminus \operatorname{diag}(R^2); \mathbb{Q})$, and $lk_G(J, K) = lk(J, K)k_G(m_f, m_J)$. Thus it suffices to prove that $lk_G(m_f, m_J) = 1$ for a positive Hopf link $(m_f, m_J)$ in a standard ball embedded in $R$. Now, there is no loss of generality in assuming that our link is a Hopf link in $\mathbb{R}^3$. So the equality follows from that for the positive Hopf link in $\mathbb{R}^3$. □

Lemma 1.15 shows in what sense propagators represent the linking number. In what follows, we will use these propagators to define invariants of $Q$–spheres.

1.4. On the Theta invariant

More on algebraic intersections. The intersection of two transverse submanifolds $A$ and $B$ in a manifold $M$ is a manifold, which is oriented so that the normal bundle to $A \cap B$ is $(N(A) \oplus N(B))$, fiberwise. In order to give a meaning to the sum $(N_x(A) \oplus N_x((B))$ at $x \in A \cap B$, pick a Riemannian metric on $M$, which canonically identifies $N_x(A)$ with $T_x(A)^\perp$, $N_x(B)$ with $T_x(B)^\perp$, and $N_x(A \cap B)$ with $T_x(A \cap B)^\perp = T_x(A)^\perp \oplus T_x(B)^\perp$. Since the space of Riemannian metrics on $M$ is convex, and therefore connected, the induced orientation of $T_x(A \cap B)$ does not depend on the choice of Riemannian metric.

Let $A, B, C$ be three pairwise transverse submanifolds in a manifold $M$ such that $A \cap B$ is transverse to $C$. The oriented intersection $(A \cap B) \cap C$ is a well-defined oriented manifold. Our assumptions imply that at any $x \in A \cap B \cap C$, the sum $(T_x(A)^\perp \oplus (T_x(B)^\perp \oplus (T_x(C)^\perp$ is a direct sum $(T_x(A)^\perp \oplus (T_x(B)^\perp \oplus (T_x(C)^\perp$ for any Riemannian metric on $M$, so that $A$ is also transverse to $B \cap C$, and $(A \cap B) \cap C = A \cap (B \cap C)$. Thus, the intersection of transverse, oriented submanifolds is a well defined associative operation, where transverse submanifolds are manifolds such that the elementary pairwise intermediate possible intersections are well defined as above. This oriented intersection is also commutative when the codimensions of the submanifolds are even.

If $A_1, \ldots, A_k$ of $M$ are transverse compact submanifolds whose codimension sum is the dimension of $M$, their algebraic intersection is defined to be $(A_1, \ldots, A_k)_M = \langle \cap_{i=1}^k A_i, A_k \rangle_M$. If $M$ is a connected manifold, which contains a point $x$, the class of a 0-cycle in $H_0(M; \mathbb{Q}) = \mathbb{Q}[x] = \mathbb{Q}$ is a well-defined number, and $(A_1, \ldots, A_k)_M$ can equivalently be defined as the homology class of the (oriented) intersection $\cap_{i=1}^k A_i$. This algebraic intersection extends multilinearly to rational chains.

Theorem 1.16. Let $(R, \tau)$ be an asymptotic rational homology $\mathbb{R}^3$. Let $P_a, P_b$ and $P_c$ be three transverse propagating chains of $(C_2(R), \tau)$ with respective boundaries $p^{-1}_\tau(a)$, $p^{-1}_\tau(b)$ and $p^{-1}_\tau(c)$ for three distinct points $a$, $b$ and $c$ of $S^2$. Then

$$\Theta(R, \tau) = (P_a, P_b, P_c)_{C_2(R)}$$

do not depend on the chosen propagators $P_a$, $P_b$ and $P_c$. It is a topological invariant of $(R, \tau)$. □
Proof: Since \( H_4(C_2(R);\mathbb{Q}) = 0 \), if the propagator \( P_a \) is replaced by a propagator \( P'_a \) with the same boundary, \((P'_a - P_a)\) bounds a 5-dimensional rational chain \( W \) transverse to \( P_b \cap P_c \). The 1-dimensional chain \( W \cap P_b \cap P_c \) does not meet \( \partial C_2(R) \) since \( P_b \cap P_c \) does not meet \( \partial C_2(R) \). Therefore, up to a well-determined sign, the boundary of \( W \cap P_b \cap P_c \) is \( P'_a \cap P_b \cap P_c - P_a \cap P_b \cap P_c \). This shows that \((P_a, P_b, P_c)_{C_2(R)}\) is independent of \( P_a \) when \( a \) is fixed. Similarly, it is independent of \( P_b \) and \( P_c \) when \( b \) and \( c \) are fixed. Thus, \((P_a, P_b, P_c)_{C_2(R)}\) is a rational function of the connected set of triples \((a, b, c)\) of distinct point of \( S^2 \). It is easy to see that this function is continuous, and so, it is constant. \( \square \)

**Lemma 1.17.** Let \( \omega_a \) and \( \omega'_a \) be two propagating forms of \((C_2(R), \tau)\), whose restrictions to \( \partial C_2(R) \) are \( p^*_{\tau}(\omega_A) \) and \( p^*_{\tau}(\omega'_A) \), respectively, for two volume-one forms \( \omega_A \) and \( \omega'_A \) of \( S^2 \). There exists a one-form \( \eta_A \) on \( C_2(R) \) such that \( \omega'_A = \omega_A + d\eta_A \). For any such \( \eta_A \), there exists a one-form \( \eta \) on \( C_2(R) \) such that \( \omega'_A - \omega_A = d\eta \), and the restriction of \( \eta \) to \( \partial C_2(R) \) is \( p^*_{\tau}(\eta_A) \).

**Proof:** Since \( \omega_a \) and \( \omega'_a \) are cohomologous, there exists a one-form \( \eta \) on \( C_2(R) \) such that \( \omega'_a - \omega_a = d\eta \). Similarly, since \( \int_{S^2} \omega'_a = \int_{S^2} \omega_a \), there exists a one-form \( \eta_A \) on \( S^2 \) such that \( \omega'_A = \omega_A + d\eta_A \). On \( \partial C_2(R) \), \( d(\eta - p^*_{\tau}(\eta_A)) = 0 \). Thanks to the exact sequence with real coefficients

\[
0 = H^1(C_2(R)) \longrightarrow H^1(\partial C_2(R)) \longrightarrow H^2(C_2(R), \partial C_2(R)) \cong H_4(C_2(R)) \cong 0,
\]

we obtain \( H^1(\partial C_2(R); \mathbb{R}) = 0 \). Therefore, there exists a function \( f \) from \( \partial C_2(R) \) to \( \mathbb{R} \) such that

\[
df = \eta - p^*_{\tau}(\eta_A)
\]

on \( \partial C_2(R) \). To obtain the result, we extend \( f \) to a \( C^\infty \) map on \( C_2(R) \) and replace \( \eta \) by \((\eta - df)\). \( \square \)

**Theorem 1.18.** Let \((\bar{R}, \tau)\) be an asymptotic rational homology \( \mathbb{R}^3 \). For any three propagating forms \( \omega_a \), \( \omega_b \) and \( \omega_c \) of \((C_2(R), \tau)\),

\[
\Theta(R, \tau) = \int_{C_2(R)} \omega_a \wedge \omega_b \wedge \omega_c.
\]

**Proof:** Let us first prove that \( \int_{C_2(R)} \omega_a \wedge \omega_b \wedge \omega_c \) is independent of the propagating forms \( \omega_a \), \( \omega_b \) and \( \omega_c \). Using Lemma 1.17 and its notation

\[
\int_{C_2(R)} \omega'_a \wedge \omega_b \wedge \omega_c = \int_{C_2(R)} \omega_a \wedge \omega_b \wedge \omega_c = \int_{\partial C_2(R)} d(\eta \wedge \omega_b \wedge \omega_c) = \int_{\partial C_2(R)} \eta \wedge \omega_b \wedge \omega_c = \int_{\partial C_2(R)} p^*_{\tau}(\eta_A \wedge \omega_b \wedge \omega_c) = 0
\]

since any 5-form on \( S^2 \) vanishes. Thus, \( \int_{C_2(R)} \omega_a \wedge \omega_b \wedge \omega_c \) is independent of the propagating forms \( \omega_a \), \( \omega_b \) and \( \omega_c \). Now, we can choose the propagating forms \( \omega_a \), \( \omega_b \) and \( \omega_c \) supported in very small neighborhoods of \( P_a \), \( P_b \) and \( P_c \) and Poincaré dual to \( P_a \), \( P_b \) and \( P_c \), respectively, so that the intersection of the three supports is a very small neighborhood of \( P_a \cap P_b \cap P_c \), from which it can easily be seen that \( \int_{C_2(R)} \omega_a \wedge \omega_b \wedge \omega_c = \langle P_a, P_b, P_c \rangle_{C_2(R)} \). See [Les20, Section 11.4, Section B.2 and Lemma B.4 in particular] for more details. \( \square \)

In particular, \( \Theta(R, \tau) \) is equal to \( \int_{C_2(R)} \omega^3 \) for any propagating form \( \omega \) of \((C_2(R), \tau)\). Since such a propagating form represents the linking number, \( \Theta(R, \tau) \) can be thought of as the cube of the linking number with respect to \( \tau \). When \( \tau \) varies continuously, \( \Theta(R, \tau) \) varies continuously in \( Q \) so that \( \Theta(R, \tau) \) is an invariant of the homotopy class of \( \tau \).

**Example 1.19.** Using (disjoint!) propagators \( p^{-1}_{S^2}(a), p^{-1}_{S^2}(b), p^{-1}_{S^2}(c) \) associated to three distinct points \( a, b \) and \( c \) of \( \mathbb{R}^3 \), as in Example 1.13, it is clear that

\[
\Theta(S^3, \tau_S) = \langle p^{-1}_{S^2}(a), p^{-1}_{S^2}(b), p^{-1}_{S^2}(c) \rangle_{C_2(S^1)} = 0.
\]
Parallelizations of 3-manifolds and Pontrjagin classes.

**Definition 1.20.** Let $SO(3)$ be the group of orientation-preserving linear isometries of $\mathbb{R}^3$. In this paragraph, we regard $S^3$ as $B^3/\partial B^3$ where $B^3$ is the standard unit ball of $\mathbb{R}^3$ viewed as $([0,1] \times S^2)/(0 \sim \{0\} \times S^2)$. Let $\chi_\pi: [0,1] \to [0,2\pi]$ be an increasing smooth bijection whose derivatives vanish at 0 and 1 such that $\chi_\pi(1-\theta) = 2\pi - \chi_\pi(\theta)$ for any $\theta \in [0,1]$. Let $\rho: B^3 \to SO(3)$ be the map that sends $(\theta \in [0,1], v \in S^2)$ to the rotation $\rho(\chi_\pi(\theta); v)$ with axis directed by $v$ and with angle $\chi_\pi(\theta)$.

This map\(^{10}\) induces the double covering $\hat{\rho}: S^3 \to SO(3)$, which identifies $SO(3)$ with the real projective space $\mathbb{R}P^3$, and which orients $SO(3)$.

For any map $g$ from $\hat{R}$ to $SO(3)$ that sends $c^3_0$ to the identity element $1_{SO(3)}$ of the group $SO(3)$, define

$$\psi_R(g): \hat{R} \times \mathbb{R}^3 \to \hat{R} \times \mathbb{R}^3 \quad (x,y) \to (x, g(x)\varphi(y)).$$

Since $GL^+(\mathbb{R}^3)$ deformation retracts onto $SO(3)$, any asymptotically standard parallelization of $\hat{R}$ is homotopic to $\tau \circ \psi_R(g)$ for some $g$ as above.

The following classical theorem is proved in [Les20, Chapter 5]. See Theorem 4.6 and Proposition 5.22 in particular.

**Theorem 1.21.** Let $(\hat{R}, \tau)$ be an asymptotic rational homology $\mathbb{R}^3$. There exists a canonical map $p_1$ from the set of homotopy classes of asymptotically standard parallelizations of $\hat{R}$ to $\mathbb{Z}$ such that $p_1(\tau_{|}) = 0$, and, for any map $g$ from $R$ to $SO(3)$ that sends $c^3_0$ to the identity element $1_{SO(3)}$ of $SO(3)$, we have

$$p_1(\tau \circ \psi_R(g(\varphi) )) - p_1(\tau) = 2\deg(g).$$

The following proposition is proved in [Les20, Section 4.3]. See Proposition 4.8.

**Proposition 1.22.** Let $(\hat{R}, \tau)$ be an asymptotic rational homology $\mathbb{R}^3$. For any map $g$ from $R$ to $SO(3)$ that sends $c^3_0$ to $1_{SO(3)}$,

$$\Theta(R, \tau \circ \psi_R(g)) - \Theta(R, \tau) = \frac{1}{2} \deg(g).$$

Theorem 1.21 allows us to derive the following corollary from Proposition 1.22.

**Corollary 1.23.** $\Theta(R) = \Theta(R, \tau) - \frac{1}{2} p_1(\tau)$ is an invariant of $Q$-spheres.

The invariant $\Theta$ coincides with $6\lambda_{CW}$ where $\lambda_{CW}$ denotes the Casson-Walker invariant. The Walker invariant generalizes the Casson invariant of $Z$-spheres, which counts the conjugacy classes of irreducible representations of their fundamental groups using Heegaard splittings. See [AM90, GM92, Mar88]. It is normalized as in [AM90, GM92, Mar88] for integer homology 3-spheres, and as $\frac{1}{2} \lambda_W$ for rational homology 3-spheres where $\lambda_W$ is the Walker normalisation in [Wal92]. The equality $\Theta = 6\lambda_{CW}$ was sketchedly proved by Kuperberg and Thurston in [KT99] for $Z$-spheres, and it was generalized to $Q$-spheres in [Les04, Section 6]. See [Les04, Theorem 2.6] or [Les20, Theorem 18.30].

The main part of the proof consists in comparing second derivatives or (variations of variations) of $\Theta$ and $\lambda_{CW}$ under the following Lagrangian-preserving surgeries.

\(^{10}\)This double covering map allows one to deduce the first three homotopy groups of $SO(3)$ from those of $S^3$. The first three homotopy groups of $SO(3)$ are $\pi_1(SO(3)) = \mathbb{Z}/2\mathbb{Z}, \pi_2(SO(3)) = 0$ and $\pi_3(SO(3)) = 2[\rho]$. For $v \in S^2$, $\pi_3(SO(3))$ is generated by the class of the loop that maps $\exp(\theta) \in S^1$ to the rotation $\rho(\theta; v)$. See [Les20, Section A.2 and Theorem A.14, in particular].
Lagrangian-preserving surgeries.

Definition 1.24. An integer (resp. rational) homology handlebody of genus \( g \) is a compact oriented 3-manifold \( A \) that has the same integral (resp. rational) homology as the usual solid handlebody \( H_g \) of Figure 1.5.

Exercise 1.25. Show that if \( A \) is a rational homology handlebody of genus \( g \), then \( \partial A \) is a genus \( g \) surface.

The Lagrangian \( \mathcal{L}_A \) of a compact 3-manifold \( A \) is the kernel of the map induced by the inclusion from \( H_1(\partial A; \mathbb{Q}) \) to \( H_1(A; \mathbb{Q}) \).

In Figure 1.5, the Lagrangian of \( H_g \) is freely generated by the classes of the curves \( a_i \).

Definition 1.26. An integral (resp. rational) Lagrangian-Preserving --or LP-- surgery \( (A'/A) \) is the replacement of an integral (resp. rational) homology handlebody \( A \) embedded in the interior of a 3-manifold \( M \) with another such \( A' \) whose boundary is identified with \( \partial A \) by an orientation-preserving diffeomorphism that sends \( \mathcal{L}_A \) to \( \mathcal{L}_{A'} \). The manifold \( M(A'/A) \) obtained by such an LP-surgery is given\(^{11}\) by

\[
M(A'/A) = (M \setminus \text{Int}(A)) \cup \partial A' A'.
\]

Lemma 1.27. If \( (A'/A) \) is an integral (resp. rational) LP-surgery in a 3-manifold \( M \), then the homology of \( M(A'/A) \) with \( \mathbb{Z} \)-coefficients (resp. with \( \mathbb{Q} \)-coefficients) is canonically isomorphic to \( H_*(M; \mathbb{Z}) \) (resp. to \( H_*(M; \mathbb{Q}) \)). If \( M \) is a \( \mathbb{Q} \)-sphere, if \( (A'/A) \) is a rational LP-surgery, and if \( (J, K) \) is a two-component link of \( M \setminus A \), then the linking number of \( J \) and \( K \) in \( M \) and the linking number of \( J \) and \( K \) in \( M(A'/A) \) coincide.

Proof: Exercise. \( \square \)

In [Les04], I computed

\[
\Theta(R(A'/A, B'/B)) - \Theta(R(A'/A)) - \Theta(R(B'/B)) + \Theta(R)
\]

and proved that it coincides with

\[
6\lambda_{CW}(R(A'/A, B'/B)) - 6\lambda_{CW}(R(A'/A)) - 6\lambda_{CW}(R(B'/B)) + 6\lambda_{CW}(R)
\]

for any two rational LP-surgeries \( (A'/A) \) and \( (B'/B) \) in a \( \mathbb{Q} \)-sphere \( R \) such that \( A \) and \( B \) are disjoint rational homology handlebodies in \( R \). Together with the property that \( \Theta(-R) = -\Theta(R) \), this implies that \( \Theta = 6\lambda_{CW} \). See [Les20, Theorem 18.28]. In order to perform the computation of the above discrete “second derivative”

\[
(\Theta(R(A'/A, B'/B)) - \Theta(R(B'/B))) - (\Theta(R(A'/A)) - \Theta(R))
\]

of \( \Theta \), I built propagators for the four involved \( \mathbb{Q} \)-spheres, which coincide in the identical parts of the configuration spaces, like \( (M \setminus (A \cup B))^2 \setminus \text{diag} \), for example.

\(^{11}\)This description defines only the topological structure of \( M(A'/A) \), but we equip \( M(A'/A) \) with its unique smooth structure.
1.5. A propagator associated to a Heegaard diagram

In this section, we give an example of a propagating chain associated to a Heegaard diagram or to a self-indexed Morse function of an asymptotic rational homology \( \mathbb{R}^3 \). I constructed such a Morse propagator with Greg Kuperberg in [Les15a]. Similar propagators associated to more general Morse functions have been constructed independently by Watanabe in [Wat18].

First note that the propagator \( A^{-1}(\vec{N}) \) of \( C_2(S^3) \) associated to the upward vertical vector \( \vec{N} \) intersects \( \mathcal{C}_2(S^3) \) as \( \{ (x, x + t\vec{N}) \mid x \in \mathbb{R}^3, t \in [0, +\infty) \} \). The explicit propagator that we are about to construct for an asymptotic rational homology \( f \) is built from the closure \( P_\phi \) in \( C_2(\mathbb{R}) \) of \( \{ (x, \phi_t(x)) \mid x \in \bar{R}, t \in [0, +\infty) \} \), where \( \phi_t \) is the flow associated to a Morse function without minima and maxima of \( f \), and to a metric \( g \) on \( \mathbb{R}^3 \).

Start with \( \mathbb{R}^3 \) equipped with its standard height function \( f_0 \) and replace the cube \( [-\frac{1}{2}, \frac{1}{2}]^2 \times [0, 1] \) with a rational homology cube \( C_R \) (which has the rational homology of a point) equipped with a Morse function \( f \), which coincides with \( f_0 \) on \( \partial \mathbb{R}^3 \), and which has \( 2g \) critical points: \( g \) points \( a_1, \ldots, a_g \) of index 1, mapped to \( 1/3 \) by \( f \), and \( g \) points \( b_1, \ldots, b_g \) of index 2, mapped to \( 2/3 \) by \( f \) (so that \( 3f \) is self-indexed). Let \( \bar{R} \) be the associated open manifold, and let \( R \) be its one-point compactification. Equip \( \bar{R} \) with a Riemannian metric \( g \) that coincides with the standard one outside \( [-\frac{1}{2}, \frac{1}{2}]^2 \times [0, 1] \).

The preimage \( H_a \) of \( [\frac{1}{2}, +\infty[ \) under \( f \) in \( C_R \) has the standard representation of the bottom part of Figure 1.6. Our standard representation of the preimage \( H_a \) of \( [\frac{1}{2}, +\infty[ \) under \( f \) in \( C_R \) is shown in the upper part of Figure 1.6. These two pieces are equipped with standard Morse functions and metrics, a few corresponding flow lines are drawn in Figure 1.7. They are glued to each other by a diffeomorphism from \( \partial H_a \) to \( (-\partial H_b) \).

![Figure 1.6: \( H_a \) and \( H_b \)](image-url)

The closure of the two-dimensional ascending manifold of \( a_i \) is denoted by \( A_i \). Its intersection with \( H_a \) is denoted by \( D(a_i) \). The disk \( D(a_i) \) and \( A_i \) are consistently oriented so that the boundary of the disk \( D(a_i) \) is the curve \( a_i \) of Figures 1.6 and 1.7. The descending manifold of \( a_i \) consists of two half-lines \( \mathcal{L}_+(a_i) \) and \( \mathcal{L}_-(a_i) \) starting as vertical lines and ending...
at \( q_i \). The half-line with the orientation of the positive normal to \( A_i \) is called \( L_+(a_i) \). Thus 
\[ L(a_i) = L_+(a_i) \cup (-L_-(a_i)) \]
is the descending manifold of \( a_i \).

Symmetrically, the closure of the two-dimensional descending manifold of \( b_j \) is denoted by \( B_j \). The \( B_j \) are assumed to be transverse to the \( A_i \) outside the critical points. The intersection \( H_B \cap B_j \) is denoted by \( D(B_j) \). The disk \( D(B_j) \) and \( B_j \) are consistently oriented so that the boundary of the disk \( D(B_j) \) is the curve \( \beta_j \) of Figures 1.6 and 1.7. The ascending manifold of \( b_j \) consists of two half-lines \( L_+(b_j) \) and \( L_-(b_j) \) starting at \( b_j \) and ending as vertical lines, the first \( L_+(b_j) \) being that whose orientation matches the orientation of the positive normal to \( B_j \). Thus 
\[ L(b_j) = L_+(b_j) - L_-(b_j) \]
is the ascending manifold of \( B_j \). See Figure 1.7. Let 
\[ [J_{ij}]_{(i,j) \in \{1, \ldots, g\}^2} = [ \{ \alpha_i, \beta_i \}_{\partial H_0} ]^{-1} \]
be the inverse matrix of the matrix of the algebraic intersection numbers \( \{ \alpha_i, \beta_i \}_{\partial H_0} \).

Let \( \phi \) be the flow associated to the gradient of \( f \) and to \( g \). Let \( P_\phi \) be the closure in \( C_2(R) \) of the image of 
\[ \{ (\hat{R} \setminus \{ \alpha_i, b_i; i \in \{1, \ldots, g\} \}) \times 0, +\infty[ \} \rightarrow C_2(R) \]
\[ (x, t) \rightarrow (x, \phi_t(x)) \].

Let \( ((B_j \times A_i) \cap C_2(R)) \) denote the closure of \( ((B_j \times A_i) \cap (\hat{R}^2 \setminus \text{diag})) \) in \( C_2(R) \), set 
\[ P_\gamma = \sum_{(i,j) \in \{1, \ldots, g\}^2} J_{ij} ((B_j \times A_i) \cap C_2(R)) \quad \text{and} \quad P(f, g) = P_\phi + P_\gamma \]

The following proposition is proved in [Les15a]. See Theorem 4.2.

**Proposition 1.28** (Kuperberg–Lescop). **The chain** \( P(f, g) \) **is a propagating chain of** \( C_2(R) \).

In particular, \( P(f, g) \) can be used to compute linking numbers as in Lemma 1.15. It suffices\(^{12}\) to correct the boundary of \( P(f, g) \) near the boundary of \( C_2(R) \) to transform \( P(f, g) \) into a propagator of \( (C_2(R), \tau) \) as in Definition 1.12.

Define a **combining** \( \hat{R} \) to be a section of \( \hat{U} \hat{R} \) which is constant on \( \hat{C}_0^C \). For such a combining \( X, \) a **propagating chain of** \( (C_2(R), X) \) **is a propagating chain** \( P \) **of** \( C_2(R) \) **such that** \( P \cap \hat{U} \hat{R} = X(\hat{R}) \). Define \( \Theta(R, X) \) to be the algebraic intersection of a propagating chain of \( (C_2(R), X) \), a propagating chain of \( (C_2(R), -X) \) and any other propagating chain. It is easy to see that \( \Theta(R, -\) \ is a homotopy invariant of combings (see [Les15a, Theorem 2.1]) and that \( \Theta(R, \tau) = \Theta(R, \tau(-, v)) \), for any unit vector \( v \) of \( \mathbb{R}^2 \). Further properties of the invariant \( \Theta(R, \cdot) \) of combings are studied in [Les15b]. An explicit formula for the invariant \( \Theta(R, \cdot) \) from a Heegaard diagram of \( R \) was discovered by the author in [Les15a]. See [Les15a, Theorem 3.8]. It was computed directly using the above definition of \( \Theta(R, \cdot) \) together with the above Morse propagators, corrected near the boundary as in [Les15a, Section 5].

\(^{12}\)This requires some work performed in [Les15a, Section 5].
2. Configuration space integrals

2.1. Jacobi diagrams and associated configuration space integrals

Definition 2.1. A uni-trivalent graph $\Gamma$ is a 6-tuple

$$(H(\Gamma), E(\Gamma), U(\Gamma), T(\Gamma), p_E, p_V)$$

where $H(\Gamma)$, $E(\Gamma)$, $U(\Gamma)$, and $T(\Gamma)$ are finite sets, which are called the set of half-edges of $\Gamma$, the set of edges of $\Gamma$, the set of univalent vertices of $\Gamma$ and the set of trivalent vertices of $\Gamma$, respectively. $p_E : H(\Gamma) \rightarrow E(\Gamma)$ is a two-to-one map (every element of $E(\Gamma)$ has two preimages under $p_E$) and $p_V : H(\Gamma) \rightarrow U(\Gamma) \cup T(\Gamma)$ is a map such that every element of $U(\Gamma)$ has one preimage under $p_V$ and every element of $T(\Gamma)$ has three preimages under $p_V$, up to isomorphism. In other words, $\Gamma$ is a set $H(\Gamma)$ equipped with two partitions, a partition into pairs (induced by $p_E$), and a partition into singletons and triples (induced by $p_V$), up to the bijections that preserve the partitions. These bijections are the automorphisms of the uni-trivalent graph $\Gamma$.

Such a uni-trivalent graph is pictured as and identified with the topological quotient of the disjoint union $\bigcup_{h \in H(\Gamma)} \psi_h([0, 1])$ of copies $\psi_h([0, 1])$ of $[0, 1]$ by the identifications

$$\psi_h(1) = \psi_k(1) \text{ if } p_E(h) = p_E(k), \text{ and, } \psi_h(0) = \psi_k(0) \text{ if } p_V(h) = p_V(k),$$

up to homeomorphism.

Definition 2.2. Let $\mathcal{L}$ be a one-manifold, oriented or not. A Jacobi diagram $\Gamma$ with support $\mathcal{L}$, also called Jacobi diagram on $\mathcal{L}$, is a finite uni-trivalent graph $\Gamma$ equipped with an isotopy class $[i_r]$ of injections $i_r$ from the set $U(\Gamma)$ of univalent vertices of $\Gamma$ into the interior of $\mathcal{L}$. For such a $\Gamma$, a $\Gamma$-compatible injection is an injection in the class $[i_r]$.

A Jacobi diagram $\Gamma$ is represented by a planar immersion of $\Gamma \cup \mathcal{L} = \Gamma \cup_{U(\Gamma)} \mathcal{L}$ where the univalent vertices of $U(\Gamma)$ are located at their images under a $\Gamma$-compatible injection $i_r$, the one-manifold $\mathcal{L}$ is represented by dashed lines, whereas the edges of the diagram $\Gamma$ are represented by plain segments. (The one-manifold $\mathcal{L}$ may be oriented in order to fix the isotopy class $[i_r]$.)

Figure 2.1 shows an example of a picture of a Jacobi diagram.

![Figure 2.1: A Jacobi diagram $\Gamma$ on the disjoint union $\mathcal{L} = S^1_1 \cup S^1_2$ of two (oriented) circles](image)

Let $(\hat{\mathcal{R}}, \tau)$ be an asymptotic rational homology $\mathbb{R}^3$. Let $\mathcal{L}$ be a one-manifold and let

$$L : \mathcal{L} \rightarrow \hat{\mathcal{R}}$$

denote a $C^\infty$ embedding from $\mathcal{L}$ to $\hat{\mathcal{R}}$. Let $\Gamma$ be a Jacobi diagram with support $\mathcal{L}$ as in Definition 2.2. Let $U = U(\Gamma)$ denote the set of univalent vertices of $\Gamma$, and let $T = T(\Gamma)$ denote the set of trivalent vertices of $\Gamma$. A configuration of $\Gamma$ is an injection

$$c : U \cup T \rightarrow \hat{\mathcal{R}}$$
whose restriction $c_U$ to $U$ may be written as $L \circ j$ for some $\Gamma$-compatible injection \[ j: U \hookrightarrow \mathcal{L}. \]

Denote the set of these configurations by $\mathcal{C}(R, L; \Gamma)$ (or $\mathcal{C}(L; \Gamma)$, when $R$ is known or is part of the data).

\[ \mathcal{C}(R, L; \Gamma) = \{ c: U \cup T \hookrightarrow \tilde{R} \mid \exists j \in \{ \Gamma \}, c |_U = L \circ j \}. \]

In $\mathcal{C}(R, L; \Gamma)$, the univalent vertices move along $L(\mathcal{L})$, while the trivalent vertices move in the ambient space $\tilde{R}$, and $\mathcal{C}(R, L; \Gamma)$ is naturally an open submanifold of $\mathcal{L}^U \times \tilde{R}^T$. When the ambient asymptotic rational homology $\mathbb{R}^3$ is $\mathbb{R}^3$, we write $\mathcal{C}(L; \Gamma) = \mathcal{C}(S^3, L; \Gamma)$.

**Examples 2.3.** For a two-component link $J \sqcup K: S^1 \sqcup S^1 \to \mathbb{R}$,

\[ \mathcal{C}(R, J \sqcup K; \emptyset; s^1_j \dashv \ldots \dashv s^1_k) = J \times K. \]

Recall that $R$ is seen as the union $R(C)$ of $c_0^C$ and of a rational homology cylinder $C$ glued along $\partial c_0$ as before Definition 1.9.

**Definition 2.4.** A long tangle representative in $\tilde{R} = \tilde{R}(\mathcal{L})$ is an embedding $L: \mathcal{L} \hookrightarrow \tilde{R}$ of a one-manifold $\mathcal{L}$, as in Figure 2.2, such that

- $L(\mathcal{L}) \cap \partial c_0 = (c^-(B^{-}) \times ]-\infty, 0]) \cup (c^+(B^{+}) \times [1, \infty[)$

for two finite sets $B^-$ and $B^+$ and two injective maps $c^-: B^- \hookrightarrow \text{Int}(D^2)$, $c^+: B^+ \hookrightarrow \text{Int}(D^2)$, which are called the bottom configuration and the top configuration of $L$, respectively, and

- $L(\mathcal{L}) \cap C$ is a compact one-manifold whose unoriented boundary is $(c^-(B^{-}) \times \{0\}) \cup (c^+(B^{+}) \times \{1\})$.

Figure 2.2: A long tangle representative (LTR) in $\mathbb{R}^3$
Definition 2.5. An orientation of a trivalent vertex of \( \Gamma \) is a cyclic order on the set of the three half-edges that meet at this vertex. An orientation of a univalent vertex \( u \) of \( \Gamma \) is an orientation of the connected component \( \mathcal{L}(u) \) of \( \mathcal{L}(u) \) in \( \mathcal{L} \), for a choice of \( \Gamma \)-compatible \( \iota_r \), associated to \( u \). This orientation is also called (and thought\(^{13}\) of as) a local orientation of \( \mathcal{L} \) at \( u \).

A vertex-orientation of a Jacobi diagram \( \Gamma \) is an orientation of every vertex of \( \Gamma \). A Jacobi diagram is oriented if it is equipped with a vertex-orientation\(^{14}\).

In the figures, the orientation of a trivalent vertex is represented by the counterclockwise order of the three half-edges that meet at the vertex. The orientation of a univalent vertex \( u \) of a Jacobi diagram on a (non-oriented) one-manifold \( \mathcal{L} \) is represented by the counterclockwise cyclic order of the three half-edges that meet at \( u \) in a planar immersion of \( \Gamma \cup \mathcal{U}(\Gamma) \mathcal{L} \), where the half-edge of \( u \) in \( \mathcal{L} \) is attached to the left-hand side of \( \mathcal{L} \), with respect to the local orientation of \( \mathcal{L} \) at \( u \), as in the following pictures.

\[
\begin{align*}
\left( \begin{array}{c}
\uparrow \\
\leftarrow \\
\rightarrow \\
\end{array} \right) & \quad \text{and} \quad \left( \begin{array}{c}
\leftarrow \\
\uparrow \\
\rightarrow \\
\end{array} \right)
\end{align*}
\]

An orientation of a set \( X \) of cardinality at least 2 is a total order of the elements of \( X \) up to an even permutation.

Cut each edge of \( \Gamma \) into two half-edges. When an edge is oriented, define its first half-edge and its second one, so that following the orientation of the edge, the first half-edge is met first. Recall that \( H(\Gamma) \) denotes the set of half-edges of \( \Gamma \). When the edges of \( \Gamma \) are oriented, the orientations of the edges of \( \Gamma \) induce the following orientation of the set \( H(\Gamma) \) of half-edges of \( \Gamma \): order \( E(\Gamma) \) arbitrarily, and order the half-edges as (first half-edge of the first edge, second half-edge of the first edge, \ldots, second half-edge of the last edge). The induced orientation of \( H(\Gamma) \) is called the edge-orientation of \( H(\Gamma) \). Note that it does not depend on the order of \( E(\Gamma) \).

Lemma 2.6. When \( \Gamma \) is equipped with a vertex-orientation, orientations of the manifold \( \hat{\mathcal{C}}(L; \Gamma) \) are in canonical one-to-one correspondence with orientations of the set \( H(\Gamma) \).

\(^{13}\)A local orientation of \( \mathcal{L} \) is simply an orientation of \( \mathcal{L}(u) \), but since different vertices are allowed to induce different orientations, we think of these orientations as being local, i.e. defined in a neighborhood of \( \iota_r(u) \) for a choice of \( \Gamma \)-compatible \( \iota_r \).

\(^{14}\)When \( \mathcal{L} \) is oriented, it suffices to specify the orientations of the trivalent vertices since the univalent vertices are oriented by \( \mathcal{L} \).
Definition 2.11. Let \( \{ (R, L; \Gamma) \} \) be a vertex-orientation of \( \Gamma \) with its vertex-orientation induced by the picture. Then the orientation of \( \Gamma \) is induced by the order of the two factors, where the first factor corresponds to the position of \( \Gamma \). Each of the factors may be labeled by an element of \( H(\Gamma) \): the \( R \)-valued local coordinate of an element of \( \Gamma \) corresponding to the image under \( j \) of an element \( u \) of \( U \) sits in the factor labeled by the half-edge that contains \( u \); the three ordered \( R \)-valued coordinates of the image under a configuration \( c \) of an element \( t \) of \( T \), with respect to an arbitrary oriented local chart, belong to the factors labeled by the three half-edges that contain \( t \), which are cyclically ordered by the vertex-orientation of \( \Gamma \), so that the cyclic orders match. □

We use Lemma 2.6 to orient \( \hat{C}(R, L; \Gamma) \) as summarized in the following immediate corollary.

Corollary 2.7. If \( \Gamma \) is equipped with a vertex-orientation \( o(\Gamma) \) and if the edges of \( \Gamma \) are oriented, then the induced edge-orientation of \( H(\Gamma) \) orients \( \hat{C}(R, L; \Gamma) \), via the canonical correspondence described in Lemma 2.6.

Example 2.8. Equip the diagram \( \bigcirc \) with its vertex-orientation induced by the picture. Orient its three edges so that they start from the same vertex. Then the orientation of \( \hat{C}(R, L; \bigcirc) \) induced by this edge-orientation of \( \bigcirc \) matches the orientation of \( (R \times \hat{R}) \) \( \cap \) \( D \) induced by the order of the two factors, where the first factor corresponds to the position of the vertex where the three edges start, as shown in the following picture.

For an integer \( k \in \mathbb{N} \), set \( k = \{ 1, 2, \ldots, k \} \).

Definition 2.9. The degree of a Jacobi diagram is half the number of all its vertices. A numbered degree \( n \) Jacobi diagram is a degree \( n \) Jacobi diagram \( \Gamma \) whose edges are oriented, equipped with an injection \( j : \tilde{E}(\Gamma) \rightarrow \mathbb{Z} \). Such an injection numbers the edges. Note that this injection is a bijection when \( U(\Gamma) \) is empty. Let \( \mathcal{D}^{(n)}(\mathcal{L}) \) denote the set of numbered degree \( n \) Jacobi diagrams with support \( \mathcal{L} \) without looped edges like \( \bigcirc \).

Examples 2.10.

\[
\begin{align*}
\mathcal{D}^{(1)}(\emptyset) &= \left\{ \begin{array}{c}
\circ \circ \\
\circ \circ \\
\circ \circ \\
\circ \circ \\
\end{array} \right\}, \\
\mathcal{D}^{(1)}(S^1) &= \mathcal{D}^{(1)}(\emptyset) \cup \left\{ \begin{array}{c}
\circ \bigcirc \\
\bigcirc \circ \\
\circ \bigcirc \\
\bigcirc \circ \\
\end{array} \right\}, \\
\mathcal{D}^{(1)}(S_1^1 \cup S_2^1) &= \mathcal{D}^{(1)}(\emptyset) \cup \left( \mathcal{D}^{(1)}(S_1^1) \setminus \mathcal{D}^{(1)}(\emptyset) \right) \cup \left( \mathcal{D}^{(1)}(S_2^1) \setminus \mathcal{D}^{(1)}(\emptyset) \right) \cup \left( \mathcal{D}^{(1)}(S_1^1 \cup S_2^1) \setminus \mathcal{D}^{(1)}(\emptyset) \right) \\
&= \left\{ s_1 \begin{array}{c}
\circ \bigcirc \\
\bigcirc \circ \\
\circ \bigcirc \\
\bigcirc \circ \\
\end{array} s_1, s_1 \begin{array}{c}
\bigcirc \circ \\
\circ \bigcirc \\
\bigcirc \circ \\
\circ \bigcirc \\
\end{array} s_1, s_1 \begin{array}{c}
\bigcirc \circ \\
\bigcirc \circ \\
\bigcirc \circ \\
\bigcirc \circ \\
\end{array} s_1, s_1 \begin{array}{c}
\bigcirc \circ \\
\bigcirc \circ \\
\bigcirc \circ \\
\bigcirc \circ \\
\end{array} s_1 \right\}.
\end{align*}
\]

Definition 2.11. Let \( \Gamma \) be a numbered degree \( n \) Jacobi diagram with support \( \mathcal{L} \). An edge \( e \) oriented from a vertex \( v_1 \) to a vertex \( v_2 \) of \( \Gamma \) induces the following canonical map

\[
p_e : \hat{C}(R, L; \Gamma) \rightarrow C_2(R),
\]

where \( \hat{C}(R, L; \Gamma) \) denotes the manifold \( \hat{C}(R, L; \Gamma) \) equipped with the orientation induced by \( o(\Gamma) \) and by the edge-orientation of \( \Gamma \), as in Corollary 2.7.

Note that the dimension of the space \( \hat{C}(R, L; \Gamma) \) is equal to the degree of the integrated form \( \int_{\hat{C}(R, L; \Gamma)} p_e^*(\omega(\tilde{e}(e))) \) since both coincide with the dimension of half-edges of \( \Gamma \).
Examples 2.12. For any three propagating forms $\omega(1)$, $\omega(2)$ and $\omega(3)$ of $(C_2(R), \tau)$,
\[
I(R, K_1 \sqcup K_j; S^1_i \sqcup S^1_j) = \hat{R}, \quad S^1_i \sqcup \cdots \sqcup S^1_j, \quad (\omega(i))_{i \in 2} = \text{lk}(K_i, K_j)
\]
and
\[
I(R, \emptyset, \hat{R}, (\omega(i))_{i \in 2}) = \Theta(R, \tau)
\]
for any numbering of the (plain) diagrams.

Definition 2.13. The involution $\mathbf{x} \mapsto (y, x)$ of $\tilde{R}^2 \setminus \text{diag}(\tilde{R}^2)$ extends to an involution $i$ of $C_2(R)$. A propagating form $\omega$ of $(C_2(R), \tau)$ is antisymmetric if $i^*\omega = -\omega$.

Recall that $i_{S^2}$ denotes the antipodal map of $S^2$. Since $i_{S^2}^*\omega_{S^2} = -\omega_{S^2}$, the standard propagating form $p_{S^2}^*(\omega_{S^2})$ of $(C_2(S^3), \tau_S)$ is antisymmetric. When the $\omega(i)$ are antisymmetric, $I(R, L, \Gamma, o(\Gamma), (\omega(i))_{i \in 3n})$ is independent of the orientation of the edges of $\Gamma$. Indeed, reversing the orientation of an edge changes the orientation of the configuration space and multiplies the integrated form by $(-1)$. For any propagating form $\omega$ of $(C_2(R), \tau)$, $\frac{1}{2}(\omega - i^*(\omega))$ is an antisymmetric propagating form $\omega$ of $(C_2(R), \tau)$.

When all the $\omega(i)$ coincide with a given propagating form $\omega$, $I(R, L, \Gamma, o(\Gamma), (\omega(i))_{i \in 3n})$ is simply denoted by $I(R, L, \Gamma, o(\Gamma), \omega)$. When $\hat{R} = \mathbb{R}^3$, and when $\omega = p_{S^2}^*(\omega_{S^2})$, we simply write $I(L, \Gamma, o(\Gamma))$ and we also omit $o(\Gamma)$ when $\Gamma$ is oriented by a picture.

The study of these configuration space integrals was initiated by the articles of Witten [Wit89], Guadagnini, Martellini and Mintchev [GMM90], Bar-Natan [BN95b] on the perturbative expansion of the Chern-Simons theory,\footnote{The relation between the perturbative expansion of the Chern-Simons theory of the Witten article and the configuration space integral viewpoint is explained by Polyak in [Pol05] and by Sawon in [Saw06].} in the case of links in $\mathbb{R}^3$, with the standard propagator $p_{S^2}^*(\omega_{S^2})$ on every edge. Let us compute some examples in this original setting.

2.2. Configuration space integrals associated to one chord

Let $K: S^1 \hookrightarrow \hat{R}$ be a smooth embedding of the circle into $\hat{R}$.

Consider the associated configuration space
\[
\tilde{C}(K; \hat{\rightarrow}) = \{ (K(z), K(z \exp(2\pi i t))) \mid z \in S^1, t \in [0, 1] \},
\]
which is naturally identified with an open annulus $S^1 \times ]0, 1[$, and set $I_0(K) = I(K, \hat{\rightarrow})$.

When $\hat{R} = \mathbb{R}^3$, the direction map
\[
d: \tilde{C}(K; \hat{\rightarrow}) \to S^2
\]
\[
(z, t) \mapsto \frac{1}{\|K(z \exp(2\pi i t)) - K(z)\|} (K(z \exp(2\pi i t)) - K(z))
\]
allows us to write
\[
I_0(K) = I(K, \hat{\rightarrow}) = \int_{\tilde{C}(K; \hat{\rightarrow})} d^*\omega_{S^2}.
\]

The annulus $\tilde{C}(K; \hat{\rightarrow})$ can be compactified to the closed annulus $C(K; \hat{\rightarrow}) = S^1 \times [0, 1]$, to which $d$ extends smoothly. The extended $d$, also denoted by $d$, maps $(z, 0) \in S^1 \times \{0\}$ (resp. $(z, 1) \in S^1 \times \{1\}$) to the direction of the tangent vector to $K$ at $z$ (resp. to the opposite direction). In particular, our integral $I_0(K)$ converges. It is the algebraic area $\int_{\tilde{C}(K; \hat{\rightarrow})} \omega_{S^2}$ of $d(C(K; \hat{\rightarrow}))$ in the following sense. The degree of $d$ is a continuous map from $S^2 \setminus d(\partial C(K; \hat{\rightarrow}))$ to $Z$, and the algebraic area of $d(C(K; \hat{\rightarrow}))$ is $\int_{S^2} \text{deg}(d)\omega_{S^2}$, which is the sum over the connected components $C$ of $S^2 \setminus d(\partial C(K; \hat{\rightarrow}))$ of the area of $C$ multiplied by the value of the degree at $C$.

Let $O$ be an embedding of the circle in the horizontal plane. The image under $d$ of the whole annulus lies in the horizontal great circle of $S^2$. Its area is zero so that $I_0(O) = 0$.

Let $K_1$ and $K_\perp$ be embeddings of $S^1$, which project to the horizontal plane as in Figure 2.4, which lie in the horizontal plane everywhere except when they cross over, and which lie in the union of two orthogonal planes.
The image of the boundary of $C(K_\pm;\rightarrow) = S^1 \times [0,1]$ in $S^2$ lies in the union of the great circles of the two planes, or more precisely in the union of the horizontal great circle and two vertical arcs as in the following figure, where the vertical arcs are the images of the restriction to the portion of $K_\pm$ that crosses over of the direction of the tangent map to $K$, and of the opposite direction.

In our example with $K_1$, the degree is constant on each side of our horizontal equator. Computing it at the North Pole $\vec{N}$ as in Subsection 1.1, we find that the degree of $d$ is $1$ on the Northern Hemisphere. One computes the degree of $d$ on the Southern Hemisphere similarly. It is also $1$.

Therefore, $I_0(K_1) = 1$. Similarly, $I_0(K_{-1}) = -1$.

An isotopy between two knot embeddings $K$ and $K_1$ is smooth map $\psi: [0,1] \times S^1 \rightarrow \mathbb{R}^3$ such that the restriction $\psi(t,\cdot)$ of $\psi$ to $\{t\} \times S^1$ is a knot embedding for any $t \in [0,1]$, $\psi(0,\cdot) = K$ and $\psi(1,\cdot) = K_1$. When there exists such an isotopy, $K$ and $K_1$ are said to be isotopic or in the same isotopy class. A knot is an isotopy class of knot embeddings. For example, $K_1$, $K_{-1}$ and $O$ are in the same isotopy class. They represent the same knot. Therefore, $I_0$ is not invariant under isotopy.

**Definition 2.14.** A knot embedding $K$ that lies in the union of the horizontal plane and a finite union of vertical planes so that the unit tangent vector to $K$ is never vertical is called almost-horizontal. An almost-horizontal embedding $K$ has a natural parallel $K_\parallel$ obtained from $K$ by pushing it down. An embedding from $S^1$ to $\mathbb{R}^3$ is of constant (resp. null) $I_\theta$-degree if the degree of the associated direction map $(d: \hat{C}(K;\rightarrow) \rightarrow S^2)$ can be extended to a constant (resp. everywhere $0$) function on $S^2$.

**Lemma 2.15.** Almost-horizontal knot embeddings have constant $I_\theta$-degree. Any knot of $\mathbb{R}^3$ may be represented by an almost-horizontal knot embedding $K$. For an almost-horizontal knot embedding $K$, $I_\theta(K) = lk(K, K_\parallel)$.

**Proof:** The writhe of an almost-horizontal knot embedding is the number of positive crossings minus the number of negative crossings of its orthogonal projection onto the horizontal plane. As in the previous examples, we see that an almost-horizontal knot embedding has a constant $I_\theta$-degree, which is its writhe. The parallel below $K_\parallel$ is isotopic in the complement of $K$ to the parallel $K_\parallel,\ell$ on the left-hand side of $K$, and the formulas of Section 1.1 show that $lk(K, K_\parallel,\ell)$ is the writhe of $K$. 

It is easy to construct an embedding of null $I_\theta$-degree in every isotopy class of embeddings of $S^1$ into $\mathbb{R}^3$, by adding kinks such as $\gamma$ or $\gamma'$ to a horizontal projection. Since $I_\theta$ varies continuously under an isotopy of $K$, for any knot $K$ of $\mathbb{R}^3$, $I_\theta$ maps the space of embeddings of $S^1$ into $\mathbb{R}^3$ isotopic to $K$ onto $\mathbb{R}$. 

I-21
For a long component (i.e. a non-compact connected component) $K$ of a long tangle representative in $\mathbb{R}^3 = \mathbb{C} \times \mathbb{R}$, define

$$I_0(K) = 2I \left( K, \frac{\omega}{|\omega|}, p_{\omega}^+ \right).$$

**Examples 2.16.** Let us compute $I_0(K_{l,i}) = 2I \left( K_{l,i}, \frac{\omega}{|\omega|}, \omega \right)$ for the long tangles of Figure 2.5, which shows their projections onto the plane $\mathbb{R} \times \mathbb{R} \subset \mathbb{C} \times \mathbb{R}$. Assume that the images of the embeddings lie in this plane everywhere, except when they cross over, so that the image of each one-component tangle lies again in the union of two orthogonal planes.

![Figure 2.5: Long tangle representatives](image)

The configuration space $\tilde{C}(K = K_{l,i})$ associated to $\Gamma = \frac{\omega}{|\omega|}$ and to $K : \mathbb{R} \mapsto \mathbb{R}^3$ is

$$\tilde{C}(K, \frac{\omega}{|\omega|}) = \{(K(t), K(u)) | (t, u) \in \mathbb{R}^2, t < u\},$$

which is naturally identified with the open triangle $\{(t, u) \in \mathbb{R}^2, t < u\}$. The direction map

$$d : \tilde{C}(K, \frac{\omega}{|\omega|}) \to S^2$$

$$(K(t), K(u)) \mapsto \frac{1}{|K(u) - K(t)|} (K(u) - K(t))$$

allows us to write

$$I_0(K) = 2I \left( K, \frac{\omega}{|\omega|} \right) = 2 \int_{\tilde{C}(K, \frac{\omega}{|\omega|})} d^*(\omega_{S^2}).$$

Again, since $K_{l,0}$ is contained in $\mathbb{R} \times \mathbb{R}$, $d$ maps $\tilde{C}(K_{l,0}; \frac{\omega}{|\omega|})$ to the vertical great circle $S^1_{\mathbb{R}}$ that contains the real direction of $C$ and $I_0(K_{l,0}) = 0$.

The configuration space $\tilde{C}(K_{l,1}; \frac{\omega}{|\omega|})$ embeds in the closed triangle

$$\tilde{C}(K_{l,1}; \frac{\omega}{|\omega|}) = \{(t, u) \in [-\infty, \infty]^2 | t \leq u\}$$

where $d$ extends. The extended $d$ maps $([-\infty] \times [-\infty, \infty]) \cup([-\infty, \infty] \times \{\infty\})$ to the vertical upward vector $\vec{N}$, and it maps $\{u, u\}$ to the unit tangent vector to $K$ at $u$ directed by $\mathbb{R}$. So far, this applies to any long $K$ that goes from bottom to top. For our $K_{l,1}$, $d$ maps the boundary of the triangle to the union of $S^1_{\mathbb{R}}$ and an arc of an orthogonal great circle. Here, the degree of $d$ is $1$ on the hemisphere behind $S^1_{\mathbb{R}}$ and it is zero in front of it so that $\int_{\tilde{C}(K_{l,1}; \frac{\omega}{|\omega|})} d^*(\omega_{S^2}) = \frac{1}{2}$ and $I_0(K_{l,1}) = 1$.

Let us now compute $I_0(K_{l,-1}) = -1$. In this case, $\tilde{C}(K_{l,-1}; \frac{\omega}{|\omega|})$ still embeds in the former closed triangle, but the map $d$ does not extend continuously at $(-\infty, \infty)$. It extends to $(-\infty) \times [-\infty, \infty]$ and it maps $\{\infty\} \times [-\infty, \infty]$ to $\vec{N}$, and it extends to $(-\infty, \infty) \times \{\infty\}$ and it maps $\{\infty\} \times \{\infty\}$ to $(-\vec{N})$, but we need to blow up the triangle at $(-\infty, \infty)$ so that $d$ extends. After such a blow-up, which transforms the closed triangle into $\tilde{C}(K_{l,-1}; \frac{\omega}{|\omega|})$, the extension of $d$ maps the boundary of $\tilde{C}(K_{l,-1}; \frac{\omega}{|\omega|})$ to the union of $S^1_{\mathbb{R}}$ and an arc of a great circle. Here, the degree of $d$ is $-1$ on the hemisphere in front of $S^1_{\mathbb{R}}$ and it is zero behind so that $I_0(K_{l,-1}) = -1$.

**Definition 2.17.** A propagating form of $(C_2(R), \tau)$ is homogeneous if its restriction to $\partial C_2(R)$ is equal to $p^+_\omega(\omega_{S^2})$ for the homogeneous volume-one form $\omega_{S^2}$ on $S^2$.

**Lemma 2.18.** Let $K : \mathbb{R} \mapsto \mathbb{R}$ be a component of a long tangle representative in an asymptotic rational homology $\mathbb{R}^3$. Let $\omega$ be a homogeneous propagating form of $(C_2(R), \tau)$. Then
\( I(R, K, \hat{\zeta}, \omega) \) is independent of the chosen homogeneous propagating form \( \omega \). (It depends on the embedding \( K \) and on \( \tau \).) It is denoted by \( \frac{1}{2} I_0(K, \tau) \).

See [Les20, Lemma 12.5 and Definition 12.6].

### 2.3. More examples of configuration space integrals

**Examples 2.19.** For any trivalent numbered degree \( n \) Jacobi diagram

\[
I(\Gamma) = I(S^3, \emptyset, \Gamma, o(\Gamma)) = 0.
\]

Indeed, \( I(\Gamma) \) is equal to

\[
\int_{(\hat{C}(S^3, \emptyset, \Gamma), o(\Gamma))} \left( \prod_{eeE(\Gamma)} p_{S^2} \circ p_e \right)^* \left( \bigwedge_{eeE(\Gamma)} \omega_{S^2} \right)
\]

where

- \( \bigwedge_{eeE(\Gamma)} \omega_{S^2} \) is a product volume form of \( (S^2)^{E(\Gamma)} \) with total volume one.

- \( \hat{C}(S^3, \emptyset; \Gamma) \) is the space \( \hat{C}_{2n}(\mathbb{R}^3) \) of injections of \( 2n \) into \( \mathbb{R}^3 \).

- the degree of \( \bigwedge_{eeE(\Gamma)} \omega_{S^2} \) is equal to the dimension of \( \hat{C}(S^3, \emptyset; \Gamma) \), and

- the map \( \left( \prod_{eeE(\Gamma)} p_{S^2} \circ p_e \right) \) is never a local diffeomorphism since it is invariant under the action of global translations on \( \hat{C}(S^3, \emptyset; \Gamma) \).

**Examples 2.20.** Let us now compute \( I(O, \Gamma, o(\Gamma), p_{S^2}^* (\omega_{S^2})) \), where \( O \) denotes the representative of the unknot of \( S^3 \), that is the image of the embedding of the unit circle \( S^1 \) of \( \mathbb{C} \), regarded as \( \mathbb{C} \times \{0\} \), into \( \mathbb{R}^3 \), regarded as \( \mathbb{C} \times \mathbb{R} \), for the following graphs \( \Gamma_1 = \bigcirc \bigcirc \bigcirc \), \( \Gamma_2 = \bigcirc \bigcirc \bigcirc \), \( \Gamma_3 = \bigcirc \bigcirc \bigcirc \), \( \Gamma_4 = \bigcirc \bigcirc \bigcirc \). For \( i \) in \( 4 \), set \( I(\Gamma_i) = I(S^3, O, \Gamma_i, o(\Gamma_i), p_{S^2}^* (\omega_{S^2})) \). Let us prove that \( I(\Gamma_1) = I(\Gamma_2) = I(\Gamma_3) = 0 \) and that \( I(\Gamma_4) = \frac{1}{8} \).

For \( i \) in \( 4 \), let \( \gamma = \Gamma_i, \) \( I(\Gamma_i) \) is equal to

\[
\int_{(\hat{C}(S^3, O, \Gamma_i), o(\Gamma_i))} \left( \prod_{eeE(\Gamma_i)} p_{S^2} \circ p_e \right)^* \left( \bigwedge_{eeE(\Gamma_i)} \omega_{S^2} \right).
\]

When \( i \in 2 \), the image of \( \prod_{eeE(\Gamma_i)} p_{S^2} \circ p_e \) lies in the subset of \( (S^2)^2 \) consisting of the pair of horizontal vectors. Since the interior of this subset is empty, \( I(\Gamma_i) = 0 \). When \( i = 3 \), the two edges that have the same endpoints must have the same direction so that the image of \( \prod_{eeE(\Gamma_i)} p_{S^2} \circ p_e \) lies in the subset of \( (S^2)^{E(\Gamma_i)} \) for which two \( S^2 \)-coordinates are identical (namely those in the \( S^2 \)-factors corresponding to that pair of edges), and \( I(\Gamma_3) = 0 \) as before.

Let us finish this series of examples by proving the following lemma.

**Lemma 2.21.** Let \( \Gamma = \Gamma_4 \). Then

\[
I(\Gamma_4) = I\left( \begin{array}{c}
\bigcirc \\
\bigcirc \\
\bigcirc \\
\bigcirc \\
\bigcirc \\
\bigcirc
\end{array} \right)^2 = I\left( S^3, O, \Gamma, o(\Gamma), p_{S^2}^* (\omega_{S^2}) \right) = \frac{1}{8}.
\]

**Proof:** Let \( G^+ \) be the set of direct triples \((X_{10}, X_{20}, X_{30})\) of \((S^2)^3\) where all vectors have positive heights. Recall that \( \iota_{S^2} \) is the antipodal map of \( S^2 \) and let \( G^- = (\iota_{S^2})^2(G^+) \). Let \( D \) be the codimension-one subspace of \((S^2)^3\) of triples of vectors such that at least one of the vectors is horizontal or the three vectors are coplanar. For any edge \( e \), let \( d_e \) denote \( p_{S^2} \circ p_e \). It is easy to see that the image of \( \hat{C}(K; \Gamma) \) under \( \left( \prod_{eeE} d_e \right) \) is contained in \( G^+ \cup (G^- \cup D \) and that the restriction of \( \left( \prod_{eeE} d_e \right) \) to the preimage of \( G^+ \) is a diffeomorphism \( h^+ \) onto \( G^+ \).

Using the orientation-reversing diffeomorphism \( h^- \) of \( \hat{C}(K; \Gamma) \) that maps a configuration to its composition by \((-\text{Id}_{S^2})\), it is also clear that the restriction of \( \left( \prod_{eeE} d_e \right) \) to the preimage of \( G^- \)
2.4. More compactifications of configuration spaces

Axelrod, Singer [AS94] and Kontsevich [Kon94] proved that the configuration space integrals $I(R, L; \Gamma, o(\Gamma), (\omega(i))_{i \in \mathbb{Z}})$ converge, when $\mathcal{L}$ is a disjoint union of circles, using compactifications $C(R, L; \Gamma)$ “À la Fulton-MacPherson” of $\check{C}(R, L; \Gamma)$, where the maps $\rho_e : \check{C}(R, L; \Gamma) \to C_2(R)$ extend smoothly so that $\int_{\check{C}(R, L; \Gamma), o(\Gamma)} p_e^*(\omega(j_e(e))) = \int_{C(R, L; \Gamma), o(\Gamma)} p_e^*(\omega(j_e(e)))$.

These compactifications are constructed as follows in [Les20, Chapter 8]. We first generalize the constructions of $C_2(R)$ and define a compactification $C_{\Gamma}(R)$ of the space $C_\Gamma(R)$ of injections of a finite set $V$ into $R$ as in [Les20, Theorem 8.4] as follows. For a non-empty $A \subseteq V$, let $\mathbb{S}_A$ be the set of maps from $V$ to $R$ that map $A$ to $\infty$ and $V \setminus A$ to $\check{R}$ injectively, and let $\text{diag} A(\check{R})$ be the set of maps $c$ from $V$ to $\check{R}$, which are constant on $A$ and which map $V \setminus A$ to $\check{R} \setminus \{c(A)\}$ injectively.

Start with $R^V$. Blow up $\mathbb{S}_V$ (which is reduced to the point $m = \infty$ such that $m^{-1}(\infty) = V$). Then for $k = \#V, \#V - 1, \ldots, 3, 2$, in this decreasing order, successively blow up the closures of the $\mathbb{S}_A(\check{R})$ such that $\#A = k$ (choosing an arbitrary order among them) and, next, the closures of the $\mathbb{S}_F(V \setminus A)$ such that $\#F = k - 1$ (again choosing an arbitrary order among them). Then the compactification $C(R, L; \Gamma)$ is the closure of $\check{C}(R, L; \Gamma)$ in $C_{\Gamma}(R)$ as in [Les20, Proposition 8.6]. It satisfies the following properties.

**Theorem 2.22.** If $L$ is a link, then the configuration space $C(R, L; \Gamma)$ is a compact manifold with boundary and corners with the following properties.

- The interior of $C(R, L; \Gamma)$, which is the complement of $aC(R, L; \Gamma)$, is $\check{C}(R, L; \Gamma)$.

- For any edge $e$ of $\Gamma$, the projection map $\rho_e : \check{C}(R, L; \Gamma) \to C_2(R)$ extends smoothly\(^\text{16}\) to $C(R, L; \Gamma)$.

- For every non-empty subset $A$ of $T(\Gamma)$, there is a codimension-one open face $F_\infty(A, L; \Gamma)$ of $C(R, L; \Gamma)$ which may be identified with the product of

  \[ \{ c : (V \setminus A) \hookrightarrow \check{R} | c_{\mid U} = L \circ j_U(c) \text{ for some } j_U(c) \in [i_U] \} \]

  by the space $\check{S}(\mathbb{R}^3, A)$ of injective maps $w$ from $A$ to $(\mathbb{R}^3 \setminus 0)$ up to dilation\(^\text{17}\), so that an element $(c, [w])$ of this face is the limit in $C(R, L; \Gamma)$ when $u$ tends to 0 of a family of injective configurations $(c, \frac{1}{u} w)_{u \in (0, \epsilon]}$, which is defined for some small $\epsilon > 0$, for a representative $w$ of $[w]$.

- For every subset $A$ of cardinality greater than 2 of $V(\Gamma)$ that intersects $U = U(\Gamma)$ as a (possibly empty) set of consecutive vertices on some component of $\mathcal{L}$ with respect to $[i_{U}]$, there is a codimension-one open face $F(A, L, \Gamma)$ which behaves as follows. Let $a \in A$ be such that $a \in A \cap U$ if $A \cap U \neq \emptyset$. Then $F(A, L, \Gamma)$ fibers over

  \[ \{ c : (V \setminus A) \cup \{a\} \hookrightarrow \check{R} | c_{\mid (U \setminus (U(\cup_{1}(A) \setminus \{a\})) = L \circ j_U(c)(U \setminus (U(\cup_{1}(A) \setminus \{a\})) \text{ for some } j_U(c) \in [i_{U}] \}. \]

\(^{16}\)See [Les20, Theorem 8.5].

\(^{17}\)Dilations are homotheties with positive ratio.
– If \( A \cap U = \emptyset \), then the fiber is the space \( \tilde{D}_A(T_{c(q)}\hat{R}) \) made of injective maps \( w_A \) from \( A \) to \( T_{c(q)}\hat{R} \) up to translation and dilation. When \( \hat{R} = \mathbb{R}^3 \), an element \((c, [w_A])\) of this face is the limit in \( C(R, L; \Gamma) \) when \( u \) tends to 0 of a family of injective configurations \((c + uw_A)_{u \in [0, \varepsilon]}\), which is defined for some small \( \varepsilon > 0 \), where \( w_A \) is a representative of \( w_A \) which maps \( a \) to zero, and \( c \) and \( w_A \) are extended to \( V \) so that \( c \) is constant on \( A \) and \( w_A \) maps \( V \setminus A \) to 0.

– If \( A \cap U \neq \emptyset \), then the fiber over \( c \) is the space of injective maps \( w_A \) from \( A \) to \( T_{c(q)}\hat{R} \) which map \( A \cap U \) to the line \( \mathbb{R}T_{c(q)}L \) through 0 directed by the tangent vector \( T_{c(q)}L \) to \( L \) at \( c(q) \), with respect to an order compatible with \( i_r \), up to dilation and translation along the line \( \mathbb{R}T_{c(q)}L \).

- The complement of the union of the faces described above in the boundary of \( C(R, L; \Gamma) \) is a finite union of manifolds of codimension at least 2 in \( C(R, L; \Gamma) \).

These faces are described more precisely in [Les20, Section 8.4]. Bott and Taubes analyzed the variations of the integrals \( I_r(K) \) when a knot \( K \) of \( \mathbb{R}^3 \) varies in its isotopy class in [BT94], using such compactifications together with their codimension-one faces, described above, which correspond to the loci where one blow-up has been performed.

In [Poi00], Sylvain Poirier used the theory of semi-algebraic sets [BCR98] to prove the convergence of the integrals for semi-algebraic long tangle representatives in \( \mathbb{R}^3 \). He proved that the closure \( C(L; \Gamma) \) of \( \tilde{C}(L; \Gamma) \) in \( C_{V(\Gamma)}(S^3) \) is a semi-algebraic set for semi-algebraic long tangle representatives \( L \) in \( \mathbb{R}^3 \). In [Les20, Chapter 14], I proved the convergence of the integrals for all long tangle representatives \( L \) in \( Q \)-spheres [Les20, Theorem 12.2] by studying the structure of the closure of \( \tilde{C}(R, L; \Gamma) \) in \( C_{V(\Gamma)}(R) \). This closure is no longer a manifold. See [Les20, Theorem 14.16].

2.5. The invariant \( Z \)

For a one-manifold \( \mathcal{L} \), \( D_n(\mathcal{L}) \) denotes the real vector space generated by the degree \( n \) oriented Jacobi diagrams on \( \mathcal{L} \) of Definition 2.2. For the circle \( S^1 \), these generators of \( D_n(S^1) \) are the diagrams \( \bigcirc \), \( \bullet \), \( \bigcirc \), \( \bullet \), \( \bigcirc \), \( \bullet \), and the diagrams obtained from them by changing some vertex orientations. For a non-necessarily oriented one-manifold \( \mathcal{L} \), \( A_n(\mathcal{L}) \) denotes the quotient of \( D_n(\mathcal{L}) \) by the following relations AS, Jacobi and STU:

\[
\text{AS (or antisymmetry): } \bigcirc \bigcirc = 0 \text{ and } \bigcirc \bigcirc \bigcirc \bigcirc = 0
\]

\[
\text{Jacobi: } \bigcirc \bigcirc \bigcirc \bigcirc = 0
\]

\[
\text{STU: } \bigcirc \bigcirc \bigcirc \bigcirc = \bigcirc \bigcirc \bigcirc \bigcirc
\]

Each of these relations relate oriented Jacobi diagrams which are identical outside the pictures (or, more exactly, which can be represented by planar immersions whose images intersect a disk as in the picture and are identical outside this disk). The quotient \( A_n(\mathcal{L}) \) is the largest quotient of \( D_n(\mathcal{L}) \) in which these relations hold. It is obtained by quotienting \( D_n(\mathcal{L}) \) by the vector space generated by elements of \( D_n(\mathcal{L}) \) of the form \( \bigcirc \bigcirc \), \( \bigcirc \bigcirc \bigcirc \bigcirc \) and \( \bigcirc \bigcirc \bigcirc \bigcirc \).

Examples 2.23. Note that diagrams with looped edges vanish in \( A_n(\mathcal{L}) \).

\[
A_1(S^1) = \mathbb{R} \bigcirc \bigcirc \bigcirc \bigcirc \oplus \mathbb{R} \bigcirc \bigcirc \bigcirc \bigcirc
\]
The cardinality of $\text{Aut}(\mathcal{A}_n(\mathcal{L}))$ denote its cardinality. Let $\text{Aut}(\mathcal{L})$ denote the set of unnumbered, unoriented degree $n$ jacob diagram with looped edges.

An automorphism of a graph $\Gamma \in D^D_n(\mathcal{L})$ is an automorphism of the underlying uni-trivalent graph, for which the permutation $\sigma$ of $U(\Gamma)$ induced by the automorphism is such that $i_r \circ \sigma$ and $i_r$ are isotopic for some (and thus any) $\Gamma$-compatible injection $i_r$. Let $\text{Aut}(\Gamma)$ denote the set of these automorphisms, and let $\#\text{Aut}(\Gamma)$ denote its cardinality.

**Examples 2.25.** The cardinality of $\text{Aut}(\longrightarrow)$ is 2, $\#\text{Aut}(\overset{\circ}{\longrightarrow}) = 1$, $\#\text{Aut}(\overrightarrow{\longrightarrow}) = 12$, $\#\text{Aut}(\overrightarrow{\overrightarrow{\longrightarrow}}) = 3$.

The following theorem is a consequence of [Les20, Theorem 7.20 and Proposition 7.26], when $L$ is a link and of [Les20, Theorem 12.7, Theorem 12.13 and Lemma 13.7] in general.

**Theorem 2.26.** Let $L$ be a long tangle representative in $\mathcal{L}$. Let $\mathcal{L}_C$ denote the set of connected components of $L$. Let $\omega$ be an antisymmetric homogeneous propagating form of $(C_2(R), \tau)$. Then

$$Z_n(\mathcal{L}, L, (I_0(K, \tau))_{K \in \mathcal{L}_C}, p_1(\tau)) = \sum_{\Gamma \in D^D_n(\mathcal{L})} \frac{1}{\#\text{Aut}(\Gamma)} I(R, L, \Gamma, \omega)[\Gamma] \in \mathcal{A}_n(\mathcal{L})$$

depends only on

- the pair $(\mathcal{C}, L \cap \mathcal{C})$ up to orientation-preserving diffeomorphisms\(^{18}\) of $\mathcal{C}$ which preserve the bottom disk $D^2 \times \{0\}$ and the top disk $D^2 \times \{1\}$, and which preserve $c^+(B^+)$ and $c^-(B^-)$ up to (global) translation and dilation,

- $I_0(K, \tau)$ for each component $K$ of $L$,

- $p_1(\tau)$,

where $I(R, L, \Gamma, \omega)[\Gamma] = I(R, L, \Gamma, \omega)[\Gamma]$ for an arbitrary orientation of $\Gamma$.

Note that the above definition of $I(R, L, \Gamma, \omega)[\Gamma]$ is consistent because the right-hand side of the above equality does not depend on $\omega(\Gamma)$. Also note that when $L$ is an almost-horizontal knot $K$ of $\mathbb{R}^3$ as in Definition 2.14, $Z_n(\mathbb{R}^3, K, I_0(K, \tau_3), p_1(\tau_3) = 0)$ depends only on $I_0(K, \tau_3) = \text{lk}(K, \mathbb{K})$ (see Lemma 2.15) and on the isotopy class of $K$, so that $Z_n$ induces an isotopy invariant of parallelized knots in $\mathbb{R}^3$.

\(^{18}\)As often in these notes, we identify an embedding and its image.
Examples 2.27. For the empty link $\emptyset$ of $\mathbb{R}^3$, $Z_n(\mathbb{R}^3, \emptyset, 0) = 0$ for all $n > 0$ and $Z_0(\mathbb{R}^3, \emptyset, 0) = [\emptyset]$. For the knot $O$ of Example 2.20, $Z_0(\mathbb{R}^3, O, 0) = \{ \cdot \cdot \cdot \}$, $Z_1(\mathbb{R}^3, O, 0) = 0$ and

$$Z_2(\mathbb{R}^3, O, 0) = \frac{1}{24} \left[ \frac{\mathcal{Q}}{2} \right] = \frac{1}{48} \left[ \frac{\mathcal{Q}}{2} \right].$$

For any two-component link $J \cup K$ of $\mathbb{R}^3$ such that $J$ and $K$ are almost-horizontal,

$$Z_1(\mathbb{R}^3, J \cup K, 0) = \frac{1}{2} \text{lk}(J, J) \left[ \{ J \} \right] + \frac{1}{2} \text{lk}(K, K) \left[ \{ K \} \right] + \text{lk}(J, K) \left[ \{ J, K \} \right].$$

If $(\tilde{R}, \tau)$ is a parallelized asymptotic rational homology $\mathbb{R}^3$, then

$$Z_1(\tilde{R}, \emptyset, p_1(\tau)) = \frac{\Theta(R, \tau)}{12} \left[ \{ \cdot \cdot \cdot \} \right].$$

Remark 2.28. Let $\omega$ be an antisymmetric homogeneous propagating form of $(C_2(R), \tau)$. The homogeneous definition of $Z_n(\tilde{R}, L, \cdot)$ above makes clear that $Z_n(\tilde{R}, L, \cdot)$ is a measure of graph configurations, where a graph configuration is an embedding of the set of vertices of a uni-trivalent graph into $\tilde{R}$, which maps univalent vertices to $L(L)$ in a constrained way. The embedded vertices are connected by a set of abstract plain edges, which represent the measuring form. The factor $\frac{1}{\text{Aut}(\Gamma)}$ ensures that every such configuration of an unnumbered, unoriented graph is measured exactly once.

Definition 2.29. A one-cycle $c$ of $S^2$ is algebraically trivial if, for any two points $x$ and $y$ outside its support, the algebraic intersection of an arc from $x$ to $y$ transverse to $c$ with $c$ is zero, or, equivalently, if the integral of any one-form of $S^2$ along $c$ is zero. A link embedding $L$ is straight (with respect to $\tau$) if the image $p_\tau(U^+K)$ of the direction of the tangent map to any component $K$ of $L$ is an algebraically trivial cycle of $S^2$. A straight knot embedding $K$ can be parallelized (or framed) by pushing it in a direction $\tau(X)$ for some $X \in S^2 \setminus (p_\tau(U^+K) \cup \iota_{S^2}(p_\tau(U^+K)))$. As a consequence of [Les20, Lemma 7.35], the isotopy class of the obtained parallel $K_{\parallel, \tau}$ is independent of such an $X$, and we have the following lemma.

Lemma 2.30. For any component $K$ of a straight link embedding $L_0(\tilde{R}, \tau) = \text{lk}(K, K_{\parallel, \tau})$.

Note that for any link representative $L$ in $\mathcal{L} \subset \tilde{R} = R(\mathcal{L})$, and for any asymptotically standard parallelization $\tau_0$ of $\tilde{R}$, there is a parallelization $\tau$ homotopic to $\tau_0$ among asymptotically standard parallelizations $\tau_0$ of $\tilde{R}$ such that $p_\tau(U^+K) = \{ \tilde{R} \}$ for any component $K$ of $L$, so that $L$ is straight with respect to $\tau$.

For a degree $n$ Jacobi diagram $\Gamma$ on $\mathcal{L}$, set

$$\zeta_{\Gamma} = \frac{(3n - \#E(\Gamma))!}{(3n)!^{2^{E(\Gamma)}}}.$$
embed in the flow lines (when the pairs of points are in the part \( P_\partial \) of \( P(f, g) \)) and some edges \( e = (v, w) \) constrain their origin vertex to belong to some descending manifold \( \mathcal{B}_l \) of an index 2 critical point and their final vertex to belong to some ascending manifold \( \mathcal{A}_l \) of an index 1 critical point, up to some corrections due to the behaviour of \( P(f, g) \) near \( \partial C_2(R) \). A similar way of counting graphs was proposed by Fukaya in [Fuk96] and further studied by Watanabe [Wat18].

The following consequence of Theorem 2.31 can be deduced from independent results of Sylvain Poirier [Poi02] and Dylan Thurston [Thu99] in the case of links in \( \mathbb{R}^3 \), with propagating chains \( \rho_{S^2}^n(X) \). For any edge \( e \), let \( d_e \) denote \( \rho_{S^2} \circ \rho_{e} \).

**Theorem 2.32.** Let \( L: \mathcal{L} \hookrightarrow \mathbb{R}^3 \) be a straight link embedding into \( \mathbb{R}^3 \). The subset \( A \) of \( (S^2)^{3n} \) consisting of the \( (X)_{e \in 3n} \) such that \( (X)_{e \in 3n} \) is a regular value of \( \prod_{e \in \mathcal{E}(\Gamma)} d_e : C(L; \Gamma) \to (S^2)^{3n} \langle (E) \rangle \) for any \( \Gamma \in \mathcal{D}^n(L) \) is open and dense, and, for any \( (X)_{e \in 3n} \in A \),

\[
Z_n(\mathbb{R}^3, L, (I_0(K), K_{\infty L})_{K_{\infty L}}, 0) = \sum_{e \in \mathcal{D}^n(L)} \zeta_\Gamma \left( \prod_{e \in \mathcal{E}(\Gamma)} d_e^{-1}(X_{I_0(e)}) \right) \langle \Gamma \rangle.
\]

This theorem tells us that \( Z_n(\mathbb{R}^3, L, (I_0(K), K_{\infty L})_{K_{\infty L}}, 0) \) behaves as an \( A_n(\mathcal{L}) \)-valued constant degree on \( (S^2)^{3n} \) and it may be proved along the following lines. Associate the map \( \Pi_\Gamma = \prod_{e \in \mathcal{E}(\Gamma)} d_e \times \mathrm{Id}_{(S^2)^{3n} \langle (E) \rangle} \) from \( C(L; \Gamma) \times (S^2)^{3n} \langle (E) \rangle \) to \( (S^2)^{3n} \) to each \( \Gamma \in \mathcal{D}^n(L) \), equipped with a fixed arbitrary orientation. By definition, for any such Jacobi diagram \( \Gamma \) equipped with an implicit vertex-orientation,

\[
I(L, \Gamma, \rho_{S^2}^*(\omega_{S^2})) = \int_{C(L; \Gamma) \langle (E) \rangle} \bigwedge d_e^*(\omega_{S^2})
\]

is the algebraic volume of the image of \( \Pi_\Gamma \). The degree \( d_\Gamma \) of \( \Pi_\Gamma \) is a continuous function on the complement of \( \Pi_\Gamma (\partial C(L; \Gamma) \times (S^2)^{3n} \langle (E) \rangle) \) in \( (S^2)^{3n} \). The degree \( d_\Gamma \) changes by \( \pm 1 \) across each wall, where a wall is a codimension-one image of a codimension-one face of \( \Pi_\Gamma (C(L; \Gamma) \times (S^2)^{3n} \langle (E) \rangle) \). Sylvain Poirier and Dylan Thurston proved independently that \( D_n = \sum_{\Gamma \in \mathcal{D}^n(L)} \zeta_\Gamma d_\Gamma \langle \Gamma \rangle \) can be extended to an \( A_n(\mathcal{L}) \)-valued constant function on \( (S^2)^{3n} \) by gluing the above walls as in the example below.

Let \( \Gamma \in \mathcal{D}^n(L) \). Let \( e(\ell) \) be an edge of \( \Gamma \) with label \( \ell \), which goes from a vertex \( v(\ell, 1) \) to a vertex \( v(\ell, 2) \). Assume that no other edge of \( \Gamma \) contains both \( v(\ell, 1) \) and \( v(\ell, 2) \). Let \( \gamma(e(\ell)) \) be the labelled edge-oriented graph obtained from \( \Gamma \) by contracting \( e(\ell) \) to a point. The labels of the edges of \( \Gamma/e(\ell) \) belong to \( 3n \setminus \{ \ell \} \), \( \Gamma/e(\ell) \) has one four-valent vertex and its other vertices are univalent or trivalent. Let \( \tilde{\gamma} = \tilde{\gamma}(\Gamma/e(\ell)) \) be the set of pairs \( (\hat{\ell}, \hat{e}(\ell)) \) where \( \hat{\ell} \in \mathcal{D}^n(L) \) and \( \hat{e}(\ell) \) is an edge of \( \hat{\ell} \) with label \( \ell \) such that \( \gamma(e(\ell)) \) is equal to \( \gamma/e(\ell) \).

Let us show that there are 6 graphs in \( \tilde{\gamma} \). Let \( a, b, c, d \) be the four half-edges of \( \Gamma/e(\ell) \) that contain its four-valent vertex. In \( \hat{\ell} \), the edge \( \hat{e}(\ell) \) joins a vertex \( v(\ell, 1) \) to a vertex \( v(\ell, 2) \). The vertex \( v(\ell, 1) \) is adjacent to the first half-edge of \( \hat{e}(\ell) \) and to two half-edges of \( \{a, b, c, d\} \). The unordered pair of \( \{a, b, c, d\} \) adjacent to \( v(\ell, 1) \) determines \( \hat{\ell} \) as an element of \( \mathcal{D}^n(L) \) and there are 6 elements in \( \tilde{\gamma} \) labelled by the pairs of elements of \( \{a, b, c, d\} \). They are \( \hat{\ell} = \hat{\ell}_{ab}, \hat{\ell}_{ac}, \hat{\ell}_{ad}, \hat{\ell}_{bc}, \hat{\ell}_{bd} \) and \( \hat{\ell}_{cd} \), equipped with the edge from \( v(\ell, 1) \) to \( v(\ell, 2) \). Three of them \( (\hat{\ell}_{ab}, \hat{\ell}_{ac} \) and \( \hat{\ell}_{ad} \) are drawn in Figure 2.6. The other ones are obtained from them by reversing the orientation of \( \hat{\ell}(\ell) \).

The face \( F(\{v(\ell, 1), v(\ell, 2)\}, L, \Gamma) \), where \( e(\ell) \) collapses, is fibered over the configuration space of \( \Gamma/e(\ell) \) with fiber \( S^2 \), which contains the (free) direction of the vector from \( c(v(\ell, 1)) \)

![Figure 2.6: \( \Gamma/e(\ell), \Gamma_{ab}, \Gamma_{ac} \) and \( \Gamma_{ad} \) around the collapsing edge](image)
3. Some properties of $Z$

Set $\mathcal{A}(\mathcal{L}) = \prod_{n \in \mathbb{N}} \mathcal{A}_n(\mathcal{L})$. We drop the subscript to denote the collection (or the sum) of the $Z_n$ for $n \in \mathbb{N}$. For example,

$$Z(\hat{R}, L, (0), p_1(\tau)) = (Z_n(\hat{R}, L, (0), p_1(\tau)))_{n \in \mathbb{N}} = \sum_{n \in \mathbb{N}} Z_n(\hat{R}, L, (0), p_1(\tau)) \in \mathcal{A}(\mathcal{L}).$$

The disjoint union of diagrams induces a commutative product on $\mathcal{A}(\emptyset)$ which maps two classes of diagrams to the class of their disjoint union. Equipped with this product, $\mathcal{A}(\emptyset)$ is a commutative algebra. The disjoint union of diagrams induces similarly an $\mathcal{A}(\emptyset)$-module structure on $\mathcal{A}(\mathcal{L})$ for any one-manifold $\mathcal{L}$.

### 3.1. On the invariant $Z$ of Q-spheres and the anomaly $\beta$

Let $\mathcal{A}_s(\emptyset)$ denote the subspace of $\mathcal{A}_s(\emptyset)$ generated by trivalent Jacobi diagrams with one connected component, set $\mathcal{A}_s(\emptyset) = \prod_{n \in \mathbb{N}} \mathcal{A}_s(\emptyset)$, and let $p^c : \mathcal{A}(\emptyset) \to \mathcal{A}(\emptyset)$ be the linear projection that maps the empty diagram and diagrams with several connected components to 0. Let $D^\emptyset_n$ denote the subset of $D^\emptyset_n(\emptyset)$ that contains the connected diagrams of $D^\emptyset_n(\emptyset)$. For $n \in \mathbb{N}$, set

$$z_n(\hat{R}, p_1(\tau)) = p^c(Z_n(\hat{R}, p_1(\tau))) = Z_n(\hat{R}, \emptyset, p_1(\tau)).$$

for some propagating form $\omega$ of $(C_2(R), \tau)$. The reader can check that

$$Z(\hat{R}, p_1(\tau)) = \exp(z(\hat{R}, p_1(\tau))).$$

The dependence on $p_1(\tau)$ of $z(\hat{R}, p_1(\tau))$ is linear, and the following proposition is a consequence of [Les20, Corollary 10.9, Proposition 10.7 and Definition 10.5].

**Proposition 3.1** (Kuperberg, Thurston [KT99]). There exists an element $\beta \in \mathcal{A}(\emptyset)$ such that $(z(\hat{R}, p_1(\tau)) = \frac{p_1(\tau)}{4} \beta)$ is independent of $\tau$ so that

$$Z(R) = Z(\hat{R}, p_1(\tau)) \exp\left(-\frac{p_1(\tau)}{4} \beta\right).$$

is an invariant of $R$. If $n$ is even, then the degree $n$ part $\beta_n$ of $\beta = (\beta_n)_{n \in \mathbb{N}}$ is zero.

Note the following proposition.

**Proposition 3.2.** Let $(\hat{R}, \tau)$ be an asymptotic rational homology $\mathbb{R}^3$, then

$$Z_1(\hat{R}, p_1(\tau)) = z_1(\hat{R}, p_1(\tau)) = \frac{\Theta(R, \tau)}{12} \left[ \begin{array}{c} \infty \\ \infty \end{array} \right].$$

in $\mathcal{A}_1(\emptyset) = \mathcal{A}_1(\emptyset; \mathbb{R}) = \mathbb{R}[\left[ \begin{array}{c} \infty \\ \infty \end{array} \right]]$. See [Les20, Section 10.2] for more details about the anomaly $\beta$, which is unknown in odd degrees greater than 1.

In [KT99], Greg Kuperberg and Dylan Thurston proved that the restriction of $Z$ to $\mathbb{Z}$-spheres is a universal finite type invariant of $\mathbb{Z}$-spheres, with respect to the Ohtsuki theory of finite type invariants for $\mathbb{Z}$-spheres [Oht96], see also [GGP01]. In [Les04], I generalized their result by proving that the restriction of $Z$ to $\mathbb{Q}$-spheres is a universal finite type invariant of $\mathbb{Q}$-spheres with respect to the Moussard theory of finite type invariants of $\mathbb{Q}$-spheres based on Lagrangian-preserving surgeries [Mou12], see [Les20, Sections 18.1 and 18.5]. This implies...
that $Z$ and the LMO invariant of Le, Murakami and Ohtsuki [LMO98] are equivalent in the sense that they distinguish the same $Q$-spheres.

### 3.2. On the invariant $Z$ of framed tangles and the anomaly $\alpha$

The product $\exp\left(-\frac{\partial_1(\tau)}{4}\beta\right)Z(\tilde{R}, L, (I_\theta(K, \tau))_{K \in L}, \rho_1(\tau))$ is actually independent of $\rho_1(\tau)$, too, so that we set

$$Z(\tilde{R}, L, (I_\theta(K, \tau))_{K \in L}, \rho_1(\tau)) = \exp\left(-\frac{\partial_1(\tau)}{4}\beta\right)Z(\tilde{R}, L, (I_\theta(K, \tau))_{K \in L}, \rho_1(\tau)).$$

**Remark 3.3.** Let $\bar{A}_n(\mathcal{L})$ be the quotient of $A_n(\mathcal{L})$ by the vector space generated by the diagrams that have at least one connected component without univalent vertices. Using the corresponding projection $\bar{\rho}: A_n(\mathcal{L}) \to \bar{A}_n(\mathcal{L})$ and setting $\bar{Z}_n = \bar{\rho} \circ Z_n$, we can write

$$Z(\tilde{R}, L, (I_\theta(K, \tau))_{K \in L}) = Z(R)\bar{Z}(\tilde{R}, L, (I_\theta(K, \tau))_{K \in L}).$$

If a one-manifold $\mathcal{L}$ is the union of two one-manifolds $\mathcal{L}_1$ and $\mathcal{L}_2$, which meet only along their boundaries, the disjoint union of diagrams again induces products from $A_j(\mathcal{L}_1) \otimes A_k(\mathcal{L}_2)$ to $A_{j+k}(\mathcal{L})$, where the required class of injections $i_{\mathcal{L}_1}, i_{\mathcal{L}_2}$ for a disjoint union of a Jacobi diagram $\Gamma_1$ on $\mathcal{L}_1$ and a Jacobi diagram $\Gamma_2$ on $\mathcal{L}_2$ is naturally induced by $[i_{\Gamma_1}]$ and $[i_{\Gamma_2}]$. View $[0, 1]$ as the union of $[0, \frac{1}{2}]$ and $[\frac{1}{2}, 1]$, together with orientation-preserving identifications of $[0, \frac{1}{2}]$ and $[\frac{1}{2}, 1]$ with $[0, 1]$. Then the above products induce an algebra structure on $A([0, 1])$. In [BN95a], Bar-Natan proved that the induced product of $A([0, 1])$ is actually commutative, and that the natural map from $A([0, 1])$ to $A(S^1)$ obtained from the identification $S^1 = [0, 1]/(0 \sim 1)$ is an isomorphism. See [Les20, Proposition 6.22]. In particular, the choice of an oriented connected component $K$ of $\mathcal{L}$ equips $A(\mathcal{L})$ with a well-defined $A([0, 1])$-module structure $\otimes_K$, induced by an orientation-preserving inclusion from $[0, 1]$ into a small part of $K$ outside the vertices.

A tangle representative is a pair $(\mathcal{C}, \mathcal{C} \cap L)$, which is simply denoted by $(\mathcal{C}, L)$ for a long tangle representative as in Definition 2.4, where we again identify the embedding $L$ and its image. Such a tangle representative is a cobordism in $\mathcal{C}$ from the bottom configuration of $L$ to the top configuration of $L$. From now on $Z$ is viewed as a map, which maps such a tangle representative, also denoted by $L$ or by $(\mathcal{C}, L)$, to an element $Z(\mathcal{C}, L) = Z(\tilde{R}(\mathcal{C}), L, (0)_{K \in L})$ of $A(\mathcal{L})$.

Note that $Z$ maps trivial braids $c(\mathcal{B}) \times [0, 1]$ of $\mathcal{C}_0$ to the class of the empty diagram, since the vertical translations act on the involved configuration spaces so that the image of $\prod_{\epsilon \in \mathcal{E}} d_\epsilon$ in $(S^2)^{\mathcal{E}(\mathcal{L})}$ of the configuration space is the image of the quotient, which is included in a subspace of codimension at least 1.

It is easy to compute the expansion $Z_{\leq 1}$ up to degree 1 of $Z$ for $\bigotimes$ and to show that

$$Z_0 \left( \bigotimes \right) = \begin{bmatrix} 1 \end{bmatrix} = 1 \quad \text{and} \quad Z_1 \left( \bigotimes \right) = \begin{bmatrix} 1 \quad 1 \end{bmatrix}$$

so that $Z_{\leq 1} \left( \bigotimes \right) = 1 + \begin{bmatrix} 1 \quad 1 \end{bmatrix}$,

where the endpoints of the tangle representative lie on $\mathbb{R} \times \{0, 1\}$. See [Les20, Lemma 12.19].

More precisely, $Z$ maps the above braid $(\alpha_1)^2$ to the exponential of an element obtained by inserting a combination $2\alpha$ of Jacobi diagrams with two free univalent vertices, which are symmetric with respect to exchanging two vertices, on the diagram with one edge between the two strands. See [Les20, Lemma 13.16]. The degree one part of $2\alpha$ is an edge between the two vertices, and it is conjectured that $2\alpha$ vanishes in degree greater than 1. Inserting $2\alpha$ on the edge of $\bigotimes$ gives rise to $2\alpha$, where $\alpha \in A([0, 1])$ is the Bott and Taubes anomaly, which controls the dependence on $I_\theta(K, \tau)$ as follows.
Theorem 3.4. Let $L$ be a long tangle representative and let $L_C$ denote the set of its connected components. The expression
\[
\prod_{K \in L_C} (\exp(-I_0(K, \tau)\alpha)_K) Z(\hat{R}, L, (I_0(K, \tau))_{K \in L_C})
\]
is independent of the $I_0(K, \tau)$. It is denoted by $Z(L, L)$. 

Here $\exp(-I_0(K, \tau)\alpha)$ acts on $Z(\hat{R}, L, (I_0(K, \tau))_{K \in L_C})$, by insertion on the component of $K$ in the source $L$ of the long tangle as indicated by the subscript $K$.

Remark 3.5. It is known that $\alpha_{2n} = 0$ for any $n \in \mathbb{N}$, and that $\alpha_3 = 0$ [Poi02, Proposition 1.4]. Sylvain Poirier also showed that $\alpha_5 = 0$ with the help of a Maple program. Furthermore, according to [Les02, Corollary 1.4], $\alpha_{2n+1}$ is a combination of diagrams with two univalent vertices (as mentioned above), and $Z(S^3, L)$ is obtained from the Kontsevich integral $Z^K$ by inserting $d$ times the plain part $2\alpha$ of $2\alpha$ on some edge of each degree $d$ connected component of a diagram. See [Les20, Section 10.3] for more about the anomaly $\alpha$, which is unknown in odd degrees greater than 6.

The precise natural definitions of parallels $K_j$ of long tangle components $K$ and of the corresponding linking numbers $lk(K, K_j)$ are given in [Les20, Section 12.2]. With these definitions, when $L = (K)_{K \in L_C}$ is framed by some $L_j = (K_j)_{K \in L_C}$, we set
\[
Z^f ((\mathcal{C}, (L, L_j))) = \prod_{K \in L_C} (\exp(lk(K, K_j)\alpha)_K) Z(\mathcal{C}, L),
\]
as in [Les20, Definition 12.12].

Let us now discuss some properties of this invariant $Z^f$ of framed tangles. The first one is the following functoriality property, which is part of [Les20, Theorem 13.12], and is proved in [Les20, Section 17.2].

Theorem 3.6. $Z^f$ is functorial: For two framed tangles $L_1 = (\mathcal{C}_1, L_1)$ and $L_2 = (\mathcal{C}_2, L_2)$ such that the top configuration of $L_1$ coincides with the bottom configuration of $L_2$, the naturally framed product $L_1 L_2$ is defined by stacking $L_2$ on top of $L_1$, (and appropriately vertically rescaling) and
\[
Z^f (L_1 L_2) = Z^f \left( \begin{array}{c}
L_2 \\
L_1 
\end{array} \right) = \left[ \begin{array}{c}
Z^f (L_2) \\
Z^f (L_1) 
\end{array} \right] = Z^f (L_1) Z^f (L_2).
\]

When applied to the case where the tangles are empty, this theorem implies that the invariant $Z$ of $Q$-spheres is multiplicative under connected sum.

3.3. Generalization to q–tangles

Here, framed tangles are framed cobordisms in $Q$-cylinders between injective configurations of points in $\mathbb{C}$ up to dilations and translations. For $K = \mathbb{R}$ or $\mathbb{C}$, and for a finite set $B$, the space $\hat{S}_B(\mathbb{K})$ of injective maps from $B$ to $K$ up to translation and dilation, may be compactified to a manifold $\tilde{S}_B(\mathbb{K})$ by first embedding $\hat{S}_B(\mathbb{K})$ in the compact space $\overline{S}_B(\mathbb{K})$ of non-constant maps from $B$ to $K$ up to translation and dilation (when $\#B \geq 2$), and then successively blowing up all the diagonals as in the beginning of Section 2.4. See [Les20, Section 8.3] for details.

Example 3.7. For $K = \mathbb{R}$ or $\mathbb{C}$, the configuration space $\hat{S}_1(\mathbb{K}) = \hat{S}_2(\mathbb{K})$ is reduced to a point. The configuration space $\hat{S}_2(\mathbb{C}) = \hat{S}_2(\mathbb{R})$ is a circle, while the configuration space $\hat{S}_2(\mathbb{R}) = \hat{S}_2(\mathbb{R})$ has two points $\{0, 1\}$ and $\{0, -1\}$, where we write elements of $\hat{S}_2(\mathbb{R})$ as elements $(c(1), \ldots, c(k))$ of $\mathbb{R}^k$ such that $c(1) = 0$ and $|c(k)| = 1$, for any $k \in \mathbb{N}$ such that $k \geq 2$. In general, $\hat{S}_k(\mathbb{R})$ and its compactification $\tilde{S}_k(\mathbb{R})$ have $k!$ components, which correspond to the orders of the $c(i)$ in $\mathbb{R}$. Denote the connected component of $\tilde{S}_k(\mathbb{R})$ where $c(1) < c(2) < \cdots < c(k)$ by $\hat{S}_{< k} \mathbb{R}$, and its closure in $\tilde{S}_k(\mathbb{R})$ by $\tilde{S}_{< k} \mathbb{R}$. Then $\tilde{S}_{< 2} \mathbb{R} = \{(0, t) \mid t \in \mathbb{R}, 0 \leq t \leq 1\}$, and

\[\text{\footnote{Because of the given symmetry of $\alpha$, there is no need to orient $K$ to define $\exp(-I_0(K, \tau)\alpha)_K$.}}\]
In general, for $k \geq 3$, the configuration space $S_{<k}(\mathbb{R})$ is a Stasheff polyhedron of dimension $(k-2)$ whose corners are labeled by non-associative words in the letter $\ast$ as in the above examples. For any integer $k \geq 2$, a non-associative word $w$ with $k$ letters represents a limit configuration $w = \lim_{t \to 0} w(t)$, where $w(t) = (w_1(t) = 0, w_2(t), \ldots, w_{k-1}(t), w_k(t) = 1)$ is an injective configuration for $t \in 0, \frac{1}{2}[, and, if $w$ is the product $uv$ of a non-associative word $u$ of length $j \geq 1$ and a non-associative word $v$ of length $(k-j) \geq 1$, $w_i(t) = tu_i(t)$ when $1 < i \leq j$ and $w_i(t) = 1 - t + tv_{i-j}(t)$ when $k > i > j$. For example, $((\ast \ast)\ast)(t) = (0, t^2, t, 1)$. In a limit configuration associated to such a non-associative word, points inside matching parentheses are thought of as infinitely closer to each other than they are to points outside these matching parentheses.

**Definition 3.8.** Define a combinatorial q–tangle as a framed tangle representative whose bottom and top configurations are on the real line, up to isotopies of $\mathcal{C}$ which globally preserve the intersection of the bottom disk $D^2 \times \{0\}$ with $\mathbb{R} \times \{0\}$ and the intersection of the top disk $D^2 \times \{1\}$ with $\mathbb{R} \times \{1\}$, equipped with non-associative words of the appropriate length associated to the bottom and top configurations. These non-associative words are called the bottom and top configurations of the combinatorial q–tangle.

Such a combinatorial q–tangle $L$ from a bottom word $w^-$ to a top word $w^+$ is thought of as the limit when $t$ tends to $0$ of the framed tangles $L(t)$ in the above isotopy class whose bottom and top configurations are $w^-(t)$ and $w^+(t)$, respectively. In [Les20, Theorem 13.8 and Remark 13.11], following Poirier [Poi00], I proved that $\lim_{t \to 0} z(L(t))$ exists and that it defines an isotopy invariant of these (framed) combinatorial q–tangles $L$. This invariant is still multiplicative under vertical composition as in Theorem 3.6, and we can now define other interesting operations.

For two combinatorial q–tangles $L_1 = (c_1, L_1)$ from $w_1^-$ to $w_1^+$ and $L_2 = (c_2, L_2)$ from $w_2^-$ to $w_2^+$, define the product $L_1 \circ L_2$ from the bottom configuration $w_1^-$ to the top configuration $w_2^+$ by shrinking $c_1$ and $c_2$ to make them respectively replace the products by $[0, 1]$ of the horizontal disks with radius $\frac{1}{2}$ and respective centers $-\frac{1}{2}$ and $\frac{1}{2}$.

**Theorem 3.9.** $z$ is monoidal: For two combinatorial q–tangles $L_1$ and $L_2$,

$$z(L_1 \circ L_2) = z\left(\begin{array}{c} L_1 \\ L_2 \end{array}\right) = z(z(L_1), z(L_2)) = z(z(L_1)) \circ z(z(L_2)).$$

Proof: This theorem can be easily deduced from the cabling property and the functoriality property of [Les20, Theorem 13.12].

We can also double a component $K$ according to its parallelization in a combinatorial q–tangle $L$. This operation replaces a component with two parallel components, with respect to the given framing, and, if this component has boundary points, it replaces the corresponding letters in the non-associative words with $\ast \ast$. The combinatorial q–tangle obtained in this way is denoted by $L(2 \times K)$.

The corresponding operation for Jacobi diagrams is the following one.

**Definition 3.10.** Let $\mathcal{L}$ be a one-manifold, and let $K$ be a connected component of $\mathcal{L}$. Let

$$\mathcal{L}(2 \times K) = (\mathcal{L} \setminus K) \cup (K^{(1)} \cup K^{(2)})$$
be the manifold obtained from \( \mathcal{L} \) by duplicating \( \mathcal{K} \), that is by replacing \( \mathcal{K} \) with two copies \( \mathcal{K}^{(1)} \) and \( \mathcal{K}^{(2)} \) of \( \mathcal{K} \), and let

\[
\pi(2 \times \mathcal{K}) : L(2 \times \mathcal{K}) \longrightarrow \mathcal{L}
\]

be the associated map, which is the identity on \(( \mathcal{L} \setminus \mathcal{K} )\), and the trivial 2-fold covering from \( \mathcal{K}^{(1)} \cup \mathcal{K}^{(2)} \) to \( \mathcal{K} \).

If \( \Gamma \) is (the class of) an oriented Jacobi diagram on \( \mathcal{L} \), then \( \pi(2 \times \mathcal{K})^* (\Gamma) \) is the sum of all diagrams on \( L(2 \times \mathcal{K}) \) obtained from \( \Gamma \) by lifting each univalent vertex to one of its preimages under \( \pi(2 \times \mathcal{K}) \). These diagrams have the same vertices and edges as \( \Gamma \) and the local orientations at univalent vertices are naturally induced by the local orientations of the corresponding univalent vertices of \( \Gamma \). This operation induces the natural linear duplication map:

\[
\pi(2 \times \mathcal{K})^* : \mathcal{A}(\mathcal{L}) \longrightarrow \mathcal{A}(L(2 \times \mathcal{K})).
\]

**Example 3.11.**

\[
\pi(2 \times 1)^* \left( \frac{q}{r} \right) = \frac{q}{r} + \frac{q}{r} + \frac{q}{r} + \frac{q}{r}
\]

We can now state the following duplication property for \( Z^J \) of [Les20, Theorem 13.12], which is proved in [Les20, Section 17.4].

**Theorem 3.12.** Let \( \mathcal{K} \) be a component of a combinatorial q–tangle \( \mathcal{L} \), then

\[
Z^J(L(2 \times \mathcal{K})) = \pi(2 \times \mathcal{K})^* Z^J(\mathcal{L}).
\]

More properties of \( Z^J \) are presented in [Les20, Theorem 13.12].

3.4. Discrete derivatives of \( Z^J \)

Since

\[
Z^J_{\leq 1}(\text{ } \text{ } \text{ } ) - Z^J_{\leq 1}(\text{ } \text{ } ) = \left[ \begin{array}{ccc} \frac{q}{r} & + & 0 \\ 0 & + & 0 \\ \end{array} \right],
\]

where the endpoints of the tangles lie on \( \mathbb{R} \times \{0, 1\} \), the above properties of \( Z^J \) allow us to completely compute \( n \)-th derivatives of \( Z_n \), where a simple derivative of \( Z_n \) is a difference \( Z_n(\text{ } \text{ } \text{ }) - Z_n(\text{ } \text{ } \text{ }) \). In particular, they imply that the restriction of \( Z \) to links in \( S^3 \) is a universal Vassiliev invariant of links as in [Les20, Section 17.6], without using the theorem mentioned in Remark 3.5.

The following \( n \)-th derivative with respect to LP-surgeries of \( Z^J \) is computed in [Les20, Theorem 18.5]. Let \( \mathcal{L} \) be a q–tangle representative in a rational homology cylinder \( \mathcal{C} \). Let \( U_{\mathcal{J}_{\leq 1}}^A(0) \) be a disjoint union of rational homology handlebodies embedded in \( \mathcal{C} \setminus \mathcal{L} \). Let \( (A^{(i)})_{i \in \mathcal{I}} \) be rational LP surgeries in \( \mathcal{C} \) as in Definition 1.26. Set \( X = [\mathcal{C}, \mathcal{L}; (A^{(i)})_{i \in \mathcal{I}}] \) and

\[
Z_n(X) = \sum_{I \in \mathcal{I}} (-1)^{|I|} Z_n(\mathcal{C}_I, \mathcal{L}),
\]

where \( \mathcal{C}_I = \mathcal{C}((A^{(0)}/A^{(i)})_{i \in \mathcal{I}}) \) is the rational homology cylinder obtained from \( \mathcal{C} \) by performing the LP-surgeries that replace \( A^{(i)} \) with \( A^{(i)} \) for \( i \in \mathcal{I} \). If \( 2n < x \), then \( Z_n(X) \) vanishes, and, if \( 2n = x \), then the expression of \( Z_n(X) \) is given in [Les20, Theorem 18.5].

This computation relies on constructions of propagating forms that coincide as much as possible\(^{20}\) for the involved manifolds. The result of this computation implies that the restriction of \( Z \) to \( Q \)-spheres is a universal finite type invariant of \( Q \)-spheres with respect to the Moussard theory of finite type invariants of \( Q \)-spheres [Mou12], as announced in Section 3.1.

\(^{20}\)The constructed forms \( \omega_I \) satisfy \( \omega_I = \omega_J \) on \( C_2((\mathcal{A}(0) \setminus \mathcal{U}_{\text{int}} A^{(0)}) \cup \mathcal{U}_{\text{edge}} A^{(0)}) \) for parts \( I \) and \( J \) of \( X \), where \( C_2(X) = p_0^2(X^2) \).
This computation has also allowed the author to compute $\tilde{Z}_2(R, K)$ for any null-homologous knot $K$ in a rational homology sphere $R$ in [Les20, Theorem 18.41], and to show that

$$\tilde{Z}_2(R, K) = \left(\frac{1}{24} - \frac{1}{2} \Delta_K'(1)\right) \left[ \frac{\Delta_K(t)}{t^2} \right],$$

where $\Delta_K$ is the Alexander polynomial of $K$, normalized so that $\Delta_K(t) = \Delta_K(t^{-1})$ and $\Delta_K(1) = 1$. This result was generalized by David Leturcq in [Let20]. See [Les20, Theorem 18.43].

3.5. Some open questions

The determination of the anomalies $\alpha$ and $\beta$ is still open. The behaviour of $\mathcal{Z}$ under Dehn surgeries has not yet been investigated. Is the invariant $\mathcal{Z}$ of $Q$-spheres obtained from the invariant $\mathcal{Z}$ of framed links in the same way as the Le-Murakami-Ohtsuki invariant [LMO98] is obtained from the Kontsevich integral?

I constructed an invariant $\tilde{Z}$ of null-homologous knots in $Q$-spheres from equivariant algebraic intersections in equivariant configuration spaces in [Les11, Les13]. This equivariant $\tilde{Z}$ lives in a more structured space of Jacobi diagrams. It shares many properties with the Kricker lift of the Kontsevich integral of [Kri00, GK04]. Does $\tilde{Z}$ lift the restriction of $\mathcal{Z}$ to null-homologous knots in $Q$-spheres as the Kricker invariant lifts the Kontsevich integral?

Heegaard splittings provide propagators as in Section 1.5. How do the invariants $\mathcal{Z}$, $\mathcal{Z}'$ and $\tilde{Z}$ relate to Heegaard-Floer homology?
